Many of the marks found on ceramics are merely the marks of painters and workman. Even when identified, they are not a sure guide to the place of manufacture, as these people would work in many different factories in the course of their careers. The throwers or "repairers" (the workers who assembled the various parts of figures, etc.) invariably used a mark scratched in the body of the ware prior to the biscuit-firing. These marks when *under* the glaze can safely be treated as genuine. A mark which has been ground in after firing, in order to deceive, will not have the characteristic burr or raised edge produced when soft clay is scratched.

Painters and gilders would generally use one of the colours in their palette or gilt to mark the wares upon which they worked. This was probably for the benefit of the management as payment was often on a piecework basis.

The marks used on English wares were applied in several different ways—by incising, impressing, painting, or by transfer-printing *under* the glaze

in blue (also in green after 1850). Marking by painting, transfer-printing, or stencilling over the glaze in enamel colours is always liable to be fraudulent as these types of mark can be added at any time after the piece has been made.

From 1842-83 many manufacturers' wares were marked with the "diamond-mark", illustrated above. This was an indication that the design had been registered with the British Patent Office. Ceramics was Class IV, indicated in the topmost section of the mark. This gave copyright protection for three years. After 1883 the mark was written as a number, *e.g.*, Rd. No. 12345.

A further indication of late wares is the inclusion of the word "England" in the mark. This was necessary to comply with the American McKinley Tariff Act of 1891. The full term "Made in England" is an indication of 20th century manufacture.

Limousin enamels, Italian wares
Sèvres and terra-cotta
Meissen
French, Italian, Spanish, English porcelain, European enamels

It was not until the adoption on Meissen porcelain in 1723 of the "K.P.M." and in 1724 of the cross-swords (from the arms of Saxony) that marks began to be used at all regularly in Europe. The placing of the mark underneath and the use of blue are clear indications that the Chinese mode was being followed. The Meissen practice was then adopted by other German and, indeed, by most porcelain factories of repute.

Throughout the 18th century the practice was never regularised, and except for a brief period in France from 1766, and two years later in the Dutch town of Delft, there was no compulsory marking of wares. The factories of repute, proud of their productions, added a recognised mark and even used it, as at Nymphenburg, as part of the decoration. Their imitators left their wares unmarked or employed a mark likely to be mistaken for a more famous one: Weesp and Tournay both adopted a version of the Meissen crossed-swords;

the torches of La Courtille, the hooks of Rauenstein, the hayforks of Rudolstadt, the "L"s of Limbach, and the "W" of Wallendorf, were all drawn in such a way as to resemble the Meissen mark.

The firm of Samson & Co. was established in Paris in 1845, claiming to make "Reproductions of Ancient Works emanating from the Museums and from Private Collections". When imitating the true hard-paste porcelain of the Far East or the Continent, Samson's wares are difficult to detect due to their being made from similar materials whereas his reproductions of such English factories as Bow, Chelsea, and Derby are more easily recognised as fakes. Unfortunately the range of Samson's marks, illustrated above, do not appear to have been regularly used, or, as is sometimes the case, the original mark has been removed by grinding or by etching away with acid, and a replica of a known genuine mark added.

Factory marks in the Western sense are practically unknown on Chinese porcelain wares, while those purporting to record the period of manufacture are so liable to be "commemorative", or even deliberately fraudulent, as to be a frequent cause of dispute among students. Marks of the Ming Chinese Emperors, Hsüan Tê, Ch'êng Hua and Chia Ching are commonly found on wares of the reign of the Ch'ing Emperor K'ang Hsi, while the reign name of K'ang Hsi himself, rare on the abundant porcelain of his period, is chiefly found on 19th- and 20th-century wares.

Under the rule of the Ming Emperors (1368–1644) the Sung ideals in pottery were largely rejected in favour of the vogue for fine-grained white porcelain heralding the beginning of a new period in Chinese ceramic history with its centre in the town of Ching-tê Chên in Kiangsi province where a new Imperial factory was started in 1369 with a prolific output of early Ming blue-and-white

and fine enamel-painted porcelain both for the court and later for general use and export.

Following the fall of the Ming Dynasty in 1644 their declining culture was revived by the Ch'ing Emperor K'ang Hsi (1662—1722) who was a great patron of the arts. The European influence of the French and Netherlandish Jesuits at his courts is seen in the Baroque character of the early Ch'ing porcelain.

There was a backward-looking tendency during the reigns of Yung-Chêng (1723–35) and Ch'i Lung (1736–95) when exact copies of the classic Sung wares and the early Ming painted porcela were made.

The Imperial porcelain of the 19th century w as a rule carefully and weakly correct in followi earlier styles and models. The factory was bu in 1853 by the T'ai-ping rebels and hardly covered before the 1911 revolution ended t Dynasty.

BANK AND PUBLIC HOLIDAYS

In addition to Good Friday and Christmas Day, there are Bank holidays in most parts of England, Wales and the Channel Islands on Easter Monday, in late Spring and late Summer (see below), and on the first weekday after Christmas (Boxing Day). The Channel Islands also observe New Year's Day and Liberation Day, May 9. Scotland observes New Year's Day, a late Spring and a late Summer holiday (see below). In addition most towns in Scotland have locally determined holidays in the Spring and Autumn. Northern Ireland observes all the English holidays and, in addition, has a holiday on St. Patrick's Day, 17 March, and on 12 July, commemorating the Battle of the Boyne (1690). Easter Tuesday is also a customary holiday for industry and trade.

The Queen's birthday (when decreed) is observed in the Customs and certain other Government establishments as a holiday.

THE SEASONS

	1969	1970
Vernal Equinox—Spring begins	Mar. 20, 8.08 p.m.	Mar. 21, 1.57 a.m.
Summer Solstice—Summer begins	June 21, 2.55 p.m.	June 21, 8.43 p.m.
Autumnal Equinox—Autumn begins	Sept. 23, 6.07 a.m.	Sept. 23, 11.59 a.m.
Winter Solstice—Winter begins	Dec. 22, 1.44 a.m.	Dec. 22, 7.36 a.m.

(These times are in B.S.T.)

QUARTER DAYS

ENGLAND, WALES, AND N. IRELAND.

Lady Day	March 25	Michaelmas	September 29
Midsummer	June 24	Christmas	December 25

SCOTLAND.

Candlemas	February 2	Lammas	August 1
Whitsun	May 15	Martinmas	November 11

HALF QUARTER DAYS

ENGLAND

February 8. | May 9. | August 11. | November 11.

GAME

Game is defined under the game laws as including hares, pheasants, partridges, grouse, heath or moor game, black game, deer, rabbits and (in Scotland) ptarmigan. The close times for game are as follows (the dates given are inclusive).

Black (or Heath) Game	Dec. 11 to Aug. 19 (Aug. 31 in Somerset, Devon, and New Forest).
Grouse (or Moor Game) and (in Scotland) Ptarmigan	Dec. 11 to Aug. 11.
Partridge	Feb. 2 to Aug. 31.
Pheasant	Feb. 2 to Sept. 30.

Deer, hares and rabbits are also protected to a limited extent.

CLOSE TIMES FOR SPORTING BIRDS

Birds for which the close season is Feb. 1 to Aug. 31 (inclusive) :—

Godwit, bar-tailed | Plover, grey | Coot | Redshank, common | Curlew (other than stone curlew) | Moorhen | Whimbrel | Plover, golden

Birds for which the close season is Feb. 1 to Aug. 31 (inclusive) (except below high water mark when it is Feb. 21 to Aug. 31 (inclusive) :

Wild duck of the following species :—

Common pochard | Long-tailed duck | Teal
Common scoter | Mallard | Tufted duck
Gadwall | Pintail | Velvet scoter
Garganey teal | Scaup-duck | Goldeneye
Shoveler | Wigeon

Wild geese of the following species :—

Bean-goose | Grey lag goose | White-fronted goose
Canada goose | Pink-footed goose

Birds for which the close season is Feb. 1 to Sept. 30 (inclusive) :—

Capercaillie | Woodcock (in Scotland Feb. 1 to Aug. 31).

Birds for which the close season is Feb. 1 to Aug. 11 (inclusive) :—

Snipe, common | Snipe, jack.

THE COUNTRY CODE

GUARD AGAINST THE RISK OF FIRE. Great damage is done every year to crops, plantations, woodlands, and heaths. A match or cigarette thrown away or a pipe carelessly knocked out, picnic fires not properly put out or lighted near dry crops, can quickly start a blaze.

FASTEN ALL GATES. If animals get out of a field they stray. As a result they may do serious damage to crops, suffer injury on the roads, or eat food that is harmful.

KEEP DOGS UNDER CONTROL. Animals are easily frightened, even by small, playful dogs. Stillbirths may be the result.

KEEP TO THE PATHS ACROSS FARM LAND. Crops are damaged by treading; flattened crops are difficult to harvest. Grass is a valuable crop.

AVOID DAMAGING FENCES, HEDGES, AND WALLS. If these are damaged, gaps will be caused. Where a man goes, an animal may follow.

LEAVE NO LITTER. Litter is not just unsightly, but often a danger as well. Broken glass and tins may injure animals and harm machinery.

SAFEGUARD WATER SUPPLIES. Countrymen often depend on wells and streams for water for themselves and for their animals.

PROTECT WILD LIFE, PLANTS, AND TREES. Wild animals should not be disturbed, plants uprooted, or trees treated roughly.

GO CAREFULLY ON COUNTRY ROADS. If there is no footpath, walkers are generally safer on the right, facing on-coming traffic. Care and patience are needed by motorists when passing farm animals.

RESPECT THE LIFE OF THE COUNTRYSIDE. Many of the machines and much of the business stock on which the farmer depends for his livelihood have to be kept in the open. Take care not to damage them.

[1] Established under agreement with the International Monetary Fund which requires that the par value of the currency of each member be expressed in terms of gold or U.S. Dollars.
[3] Official rate.
[5] Free market rate.
[4] Not necessarily the effective rate for all transfers.
[5] Basic rate.
[6] Provisional free market rate.

THERMOMETER COMPARISONS

Centigrade, 100°	Fahrenheit, 212°	Centigrade, 100°	Fahrenheit 212°
95	203	20	68
90	194	15·5	60
85	185	12·8	55
78·9	174	10	50
75	167	7·2	45
70	158	5	41
65	149	1·7	35
60	140	0	32
55	131	− 1·1	30
52·8	127	− 5	23
50	122	− 6·7	20
45	113	− 10	14
42·2	108	− 12·2	10
40	104	− 15	5
36·7	98	− 17·8	0
35	95	− 20	− 4
32·2	90	− 25	− 13
30	86	− 30	− 22
26·7	80	− 35	− 31
25	77	− 40	− 40

To reduce Fahrenheit to Centigrade, subtract 32 degrees and multiply by 5/9; to reduce Centigrade to Fahrenheit, multiply by 9/5 and add 32 degrees.

An alternative method, perhaps easier to remember, is to add 40 to the given figure, multiply by 5/9 (°F to °C) or 9/5 (°C to °F) and subtract 40.

UNIVERSITY DEGREES—COLOURS OF HOODS

Aberdeen

M.A.	Black silk, lined with white silk.
M.Litt.	White silk, lined with violet silk.
D.Litt.	Scarlet cloth, lined with white silk.
Ph.D.	Scarlet cloth lined with black ribbed silk the ribs running horizontally.
B.Ed.	Black silk, lined with orange silk.
M.Ed.	White silk, lined with orange silk.
B.Sc.	Black silk, lined with green silk.
B.Sc.Agr.	Black silk, edged with green silk.
B.Sc.For.	Black silk, edged with waved green silk.
BSc.Eng.	Black silk, edged with green silk and bordered inside, within the green edging, with white cloth (¼").
M.Sc.	White silk, lined with green silk.
D.Sc.	Scarlet cloth, lined with green silk.
B.D.	Black silk, lined with purple silk, and bordered inside with white silk (1").
M.Th.	White silk, lined with purple silk.
D.D.	Scarlet cloth, lined with purple silk.
LL.B.	Black silk, lined with pale blue silk.
LL.D.	Scarlet cloth, lined with pale blue silk.
M.B., Ch.B.	Black silk, lined with crimson silk.
M.D.	Scarlet cloth, lined with crimson silk.
Ch.M.	White silk, lined with crimson silk.

Note.—All the hoods of this University are of uniform pear shape of a cloth or silk foundation and lined or edged with the colour peculiar to the Faculty or Degree.

Aston

B.Sc.	Black, faced with 3" red silk interwoven with University crest.
M.Sc.	Like B.Sc. but fully lined.
Ph.D.	University red, faced as for B.Sc.
D.Sc.	Like Ph.D. but fully lined.

Bath

B.Sc. } B.Pharm. }	Old-gold lined olive-green taffeta.
B.Arch.	Old-gold lined olive-green taffeta with ½" dark red edging.
M.Sc. } M.Pharm. }	Old-gold lined pale-blue taffeta.
M.Arch.	Old-gold lined pale-blue taffeta with ½" dark red edging.
Ph.D.	Old-gold lined medium-crimson taffeta.
D.Sc.	Old-gold lined scarlet taffeta.
LL.D.	Old-gold lined scarlet taffeta with ½" white edging.

Belfast, The Queen's University

B.A.	Black ribbed silk edged with white fur and the neck edged with blue watered silk.
M.A.	Black ribbed silk lined with blue silk and edged with blue watered silk.
D.Litt.	Scarlet superfine cloth lined with white silk and edged with blue watered silk.
B.D.	Black ribbed silk lined with white silk and edged with blue watered silk.
M.Th.	Red silk lined with black silk and edged with blue watered silk.
D.D.	Scarlet superfine cloth lined with black silk and edged with blue watered silk.
LL.B.	Black ribbed silk lined with pink silk and edged with blue watered silk.
LL.M.	Royal blue ribbed silk, lined with pink silk and edged with blue watered silk.
LL.D.	Scarlet superfine cloth lined with pink silk and edged with blue watered silk.
M.B., B.Ch., B.A.O.	Black ribbed silk lined with scarlet silk and edged with blue watered silk.
M.Ch.	Red ribbed silk lined with white silk and edged with blue watered silk.
M.D.	Scarlet superfine cloth lined with scarlet silk and edged with blue watered silk.
M.A.O.	Black ribbed silk lined with purple silk and edged with blue watered silk
B.Ed.	Black ribbed silk lined with mauve silk and edged with blue watered silk.
B.Mus.	Blue silk lined with white silk and edged with blue watered silk.
D.Mus.	Scarlet superfine cloth lined with blue silk and edged with blue watered silk.
Ph.D.	Scarlet superfine cloth lined with violet silk and edged with blue watered silk.
B.Sc.	Black ribbed silk lined with green silk and edged with blue watered silk.
M.Sc.	Red ribbed silk lined with green silk and edged with blue watered silk.
D.Sc.	Scarlet superfine cloth lined with green silk and edged with blue watered silk.
B.Sc.(Econ.)	Black ribbed silk lined with rose pink silk and edged with blue watered silk.
M.Sc.(Econ.)	Rose pink silk lined with white silk edged with blue watered silk.
B.D.S.	Black ribbed silk lined with dove-grey and edged with blue watered silk.
M.D.S.	Scarlet ribbed silk lined with dove-grey and edged with blue watered silk.
B.Agr.	Black ribbed silk lined with primrose and edged with blue watered silk.
M.Agr.	Red ribbed silk lined with primrose and edged with blue watered silk.

Note.—Bachelors' and Masters' hoods are of the sim shape and Doctors' of the full shape. All the hoods ha the neck portion at least edged with the pale blue wate silk peculiar to this University.

Birmingham

B.Sc.	Black, edged with silver-grey watered s
M.Sc.	Black, lined with silver-grey watered s
D.Sc.	Scarlet, lined with silver-grey watered s
Ph.D.	Crimson, lined with silver-grey wate silk.
B.A.	Black, edged with electric-blue wate silk.
M.A.	Black, lined with electric-blue wate silk.
B.Ed.	Black, edged with primrose yellow wate silk.
D.Litt.	Scarlet, lined with electric-blue wate silk.
Ph.D.	Crimson, lined with electric-blue wate silk.
B.Mus.	Black, edged with tangerine watered s
M.Mus.	Black, lined with tangerine watered s
D.Mus.	Scarlet, lined with tangerine watered s
B.D.	Black, edged with cobalt-blue watered s
D.D.	Scarlet, lined with cobalt-blue water silk.
M.B., Ch.B.	Black, edged with cardinal watered silk
Ch.M.	Black, lined with cardinal watered silk.
M.D.	Scarlet, lined with cardinal watered silk
Ph.D.	Crimson, lined with cardinal watered s
B.D.S.	Black, edged with dark-red (Gren watered silk.
M.D.S.	Black, lined with dark-red (Gren watered silk.
B.Com.	Black, edged with terracotta watered s
B.Soc.Sc.	Black, edged with terracotta watered and bound with grey silk at top edge
M.Com.	Black, lined with terracotta watered edged with grey watered silk.
Ph.D.	Crimson, lined with terracotta wate silk.
D.Soc.Sc.	Scarlet, lined with terracotta watered and bound with grey silk at top edge
LL.B.	Black, edged with bronze-green wate silk.
LL.M.	Black, lined with bronze-green wate silk.
Ph.D.	Crimson, lined with bronze-green wate silk.
LL.D.	Scarlet, lined with bronze-green wate silk.

Note:—All hoods are of the full shape and all capes ha well-rounded corners.

Bradford

Bachelors (B.A., B.Sc., B. Tech.)	Black, edged 3" saffron.
Masters	Black, edged and fully lined saffron.
Ph.D.	Scarlet, fully lined saffron.
Higher Doctorates:	
Technology	Scarlet, fully lined saffron, edged on ins 1½" violet.
Science	Scarlet, fully lined saffron, edged on ins 1½" blue.
Literature	Scarlet, fully lined saffron, edged on ins 1½" white.

M.Sc.	cloth fully lined with cream silk, of the
M.Agr.Sc.	shape, except Ph.D., which is of crim
D.Sc.	cloth lined with cream silk (mar
Ph.D.	Russell-Cord is generally used).

St. Andrews

M.A.	Black, cherry lining.
B.D.	Wood violet, white fur edging.
B.L.	Pimento, white edging.
LL.B.	Pimento, white fur edging.
LL.D.	Pimento, white lining (satin).
Mus.D.	Cerulean blue silk or cloth with a wh lining (satin).
Ph.D.	Nanking blue, white lining (satin).
B.Sc.	Purple lilac, white fur edging.
M.Sc.	Black, purple-lilac lining.
D.Sc.	Purple lilac, white lining (satin).
B.Litt.	Saffron yellow, white fur edging.
D.Litt.	Saffron yellow, white lining (silk).

Note:—All hoods of this University are of the full sh with well-rounded capes.

Salford

Bachelors	Light "university-blue," lined gold faced 2" faculty colour.
Masters	Light "university-blue," lined gold faced 3" faculty colour.
Ph.D.	Light blue, lined and edged scarlet.
Doctors	Dark blue, lined and edged gold.

Note:—All the hoods are of the special full shape Aberdeen). Faculty colours had not been chosen at time of going to press.

Sheffield

B.A.	Green, white fur and crushed strawber
M.A.	Green and crushed strawberry.
Litt.D.	Red and crushed strawberry.
B.Mus.	Green, white fur and cream (brocade).
D.Mus.	Red and cream (brocade).
B.Ed.	Green, white fur and crushed strawbe (Arts) or apricot (Pure Science).
B.Sc.	Green, white fur and apricot.
M.Sc.	Green and apricot.
D.Sc.	Red and apricot.
M.B., Ch.B.	Green, white fur and red.
Ch.M.	Green and red.
M.D.	Red and red.
B.D.S.	Green, white fur and pale rose pink.
M.D.S.	Green and pale rose pink.
LL.B.	Green, white fur and pale green.
LL.M.	Green and pale green.
LL.D.	Red and pale green.
B.Jur.	Green, white fur and olive green.
B.Eng.	Green, white fur and purple.
M.Eng.	Green and purple.
D.Eng.	Red and purple.
B.Met.	Green, white fur and steel grey.
M.Met.	Green and steel grey.
D.Met.	Red and steel grey.
B.Sc.Tech.	Green, white fur and lilac.
M.Sc.Tech.	Green and lilac.
D.Sc.Tech.	Red and lilac.
B.A.Econ.	Green, white fur and lemon yellow
M.A.Econ.	Green and lemon yellow.
Litt.D.Econ.	Red and lemon yellow.
B.A.	(Arch. Studies) Green, white fur and gold.
M.A.	(Arch. Studies) Green and old gold.
Ph.D.	Red and dark green.

Note:—All hoods of this University are of the full sh

M.Sc. (Social Sciences)	outside with the Faculty colour except
LL.M., in which case the lining silk is
D.Sc. (Social Sciences)	turned over ¾" on the outside to make the
B.Ed.	edging, and M.Phil. where the ¾" edging
M.Phil. (in all faculties)	to the cowl portion is of claret-coloured silk. The cape of Masters' hoods is edged
Ph.D. (in all Faculties)	¾" with the peacock-blue lining silk. All Ph.D. hoods are of claret-coloured cloth fully lined with peacock-blue silk. All the Higher Doctors' hoods are of scarlet super-fine cloth fully lined with peacock-blue silk. All Doctors' hoods (inc. Ph.D.) are of the improved Oxford D.D. shape.

Strathclyde

B.A.	Blue, lined with white silk.
B.Sc.	Blue, lined with gold silk.
B.Arch.	Blue, lined with gold silk, bound with scarlet cord.
M.B.A.	Blue, lined and edged with white silk bound with black cord.
M.A.	Blue, lined with white silk with a ¾" edging of white silk.
M.Sc.	Blue, lined with gold silk with a ¾" edging of gold silk
M.Litt.	Blue, lined and edged with white silk, bound with scarlet cord.
M.Arch.	Blue, lined with white silk with a ¾" edging of gold silk.
Ph.D.	As for B.A., B.Sc., B.Arch. (as appropriate).
D.Sc.	As for B.Sc., B.Arch. (as appropriate).
D.Litt.	As for B.A.
LL.D.	(*honoris causa* only) Blue, lined with white silk, bound with scarlet cord.

Note:—All hoods are of the full shape, of saltire blue (*i.e.*, the blue of the St. Andrew flag).

Surrey

B.Sc.	Black cloth.
M.Sc.	Black cloth.
M.Phil.	Black cloth with blue rayon damask edging.
Ph.D.	Cardinal red cloth.
D.Sc.	Gold rayon satin.

Note:—All the hoods of this University are fully lined with blue rayon damask and except for the B.Sc. hood, which is modified similar to simple Oxford, are all of uniform parabolic shape.

Sussex

B.A., B.Sc.	Black cloth lined with grey fur in squares and edged with 1" band of silk in school colour.
M.A., M.Sc.	Black alpaca lined with dove grey silk with edge bound in school colour.
M.Phil.	Black alpaca lined with dove grey silk with 1" band of scarlet silk over lining set in ¾" from edge.
D.Phil., LL.D., D.Sc., D.Litt.	No hood but a distinctive gown is prescribed.

Wales

B.A.	Black and green shot blue (3").
M.A.	Black and green shot blue.
LL.B.	Black and purple shot red (3").
LL.M.	Black silk lined with red silk shot with purple.
LL.D.	Scarlet and purple shot red.
M.B., B.Ch.	Black and black shot green and white.
M.Ch.	Black and shot green edged white.
M.D.	Scarlet and black shot green and white.
B.Mus.	Blue and pearl silk lining to a depth of 3".
M.Mus.	Blue silk fully lined with pearl-coloured silk.
B.D.S., M.D.S.	Black and shot saxe blue edged purple.
B.Pharm., M.Pharm.	Black and shot saxe blue.
D.Mus.	Scarlet and pearl.
B.Sc.	Black and black shot yellow.
M.Sc.	Black and black shot yellow (3").
D.Sc.	Scarlet and black shot yellow.
Ph.D.	Crimson and Faculty colour.
D.Litt.	Scarlet and green shot blue.

Note:—Bachelors' hoods are of the simple shape, Masters' and Doctors' hoods are of the full shape.

St. David's College, Lampeter.

B.D.	Black silk, lined with violet and edged with white silk.
B.A.	Black stuff or silk, edged on inside and bound with miniver.

Note:—Both of Cambridge pattern.

York

B.A.	Grey with white edging.
B.Phil.	Grey with red edging.
M.Phil.	Red with grey edging.
D.Phil.	Red with grey lining.
D.Univ.	Red with grey lining. (hon. degree)

THE BEAUFORT SCALE OF WIND FORCE

Beaufort number	*Wind*	*Effect on land*	*Speed*	
			M.p.h.	*Knots*
0	Calm	Smoke rises vertically	Less than 1	Less than 1
1	Light air	Direction shown by smoke but not by wind vanes	1-3	1-3
2	Light breeze	Wind felt on face; leaves rustle; wind vanes move	4-7	4-6
3	Gentle breeze	Leaves and twigs in motion; wind extends light flag	8-12	7-10
4	Moderate breeze	Raises dust, loose paper and moves small branches	13-18	11-16
5	Fresh breeze	Small trees in leaf begin to sway	19-24	17-21
6	Strong breeze	Large branches in motion; whistling in telegraph wires; difficulty with umbrellas	25-31	22-27
7	Moderate gale	Whole trees in motion; difficult to walk against wind	32-38	28-33
8	Fresh gale	Twigs break off trees; progress impeded	39-46	34-40
9	Strong gale	Slight structural damage occurs; chimney pots and slates blown off	47-54	41-47
10	Whole gale	Trees uprooted and considerable structural damage	55-63	48-56
11	Storm	Widespread damage, seldom experienced in England	64-75	57-65
12	Hurricane	Winds of this force only encountered in tropical revolving storms	Above 75	Above 65

zirconium (Zr)	40	91·22	4

* In the cases of these elements, which are very rare or not found in nature, but have been a ficially prepared, atomic weight in the chemical sense is meaningless; the integral mass of the m stable isotope known is given.

Note: In 1961 the isotope of Carbon-14 replaced Oxygen as a standard, the weight of its atom be taken as exactly 12. This change of standard has meant a slight adjustment in atomic weights fr the old chemical scale.

The new elements with an atomic number higher than that of uranium 238 (element 92) are terr Transuranics.

GAS LAWS

Boyle's Law (1662) $pV = \text{constant}$.

Charles' Law (1787) $\frac{pV}{T} = \text{constant}$.

Van der Waal's equation $\left(p+\frac{a}{V^2}\right)(V-b) = RT$ where a and b are constants.

Adiabatic expansion of a gas $pV^\gamma = \text{constant}$ where $\gamma = \frac{C_p}{C_v}$.

MEDICAL MATTERS

PART I. INTRODUCTION.

(a) HOW TO USE THE SECTION.

Diseases do not exist in watertight compartments, but doctors arrange them according either to their cause or the area of the body affected. This plan has been followed here, and at the beginning of each part an account of the group of diseases under discussion is given. Unless you know enough already, you would be wise to read it.

Here is some advice about your attitude to disease in general, and your use of this section in particular.

First of all, and obviously, no book is a substitute for the doctor, and when you are ill you must see him. There are good and bad doctors, impetent and incompetent ones, just as in any other profession or trade; so choose a doctor you can trust, *and then believe what he tells you and carry out his advice.* There is no use complaining about the whole medical profession just because you are dissatisfied with your own G.P. If you have, you should change him.

Secondly, *never* believe what you hear from non-medical sources. Literally millions of people are made miserable every year by taking to heart nonsense told them by others, who may well be quite unaware of the harm they do, or even have the very best intentions. In any medical matter ask your doctor, and ignore your next-door neighbour's asked-for or unasked-for advice. Doctors are sometimes wrong, but they are much less likely to be wrong than someone without a medical education. Remember, too, that the statement that there is no cure for a disease does not necessarily mean that it is deadly: and it never means that nothing can be done to make it more tolerable. There is much more to modern doctoring than simply curing the curable.

Thirdly, don't try to diagnose your own trouble or decide what treatment you think you should have. This section will have failed completely in its intentions if it puts you in the position of a character described by an English humourist, who, from a medical dictionary, discovered that he had every disease listed in it with the solitary exception of housemaid's knee. Diseases which appear to the layman to have the "same" symptoms may be vastly different in seriousness: influenza and poliomyelitis, for example, may in the initial stages, appear very similar. So also may stomach ulcer and cancer of the stomach. No human being is infallible, but it is most important that you should go to the person who is best fitted to know—your doctor.

Lastly, you should not be misled into thinking that you can always tell the seriousness of a disease by the general appearance of the patient. Children, in particular, may have a high temperature, or even be delirious, on one day, and the next be out of bed and wanting to get back to school. On the other hand, many of the most dangerous fevers (as we shall see later) are accompanied by a low temperature and do not appear particularly dramatic in the initial stages. Thus a young woman who may be aware of nothing wrong but lack of energy and getting easily tired may be dangerously ill with tuberculosis of the lungs.

The best rule is to seek medical advice either when you have suddenly become ill with symptoms you don't understand or (and this is equally important) if you have gradually been feeling less fit over a period of time. Perhaps, too, it is wise to call your doctor if you have been ill with *anything* for more than three days. You should *not* call in a specialist before seeing your G.P., as is so often done in America and on the Continent. Specialists are very clever, but are naturally prejudiced in favour of their own subject: for example, an eye specialist will be predisposed to think of your headache in terms of eyestrain, an ear, nose, and throat specialist in terms of sinus trouble, and a psychiatrist in terms of mother-in-law trouble. Therefore you should first have a check from your G.P., who knows a little of all these things and probably a great deal about you and your past history. He will then advise you about a specialist if necessary.

(b) NEW VIEWS ON MEDICINE

(1) **Body and Mind.** In former times, or, at least during the nineteenth century, the body was regarded as a sort of machine belonging to you in much the same way that you own your watch. You went to your doctor and, in effect, said: "Now what on earth are you going to do about my stomach?"—and you spoke as if, somehow, your stomach didn't have anything to do with the *real* you—it was just an awkward thing that happened to be annoying you. But we know now that this is not so—that your body *is* you, that it is a fort fighting against such enemies as poisons, parasites, germs, cancer, and injuries. The defences are seriously weakened by not enough of the right kind of food, insufficient sleep, or by anxiety. Your anxieties and worries can kill you just as surely as the other agents, and can prevent recovery or retard it when you are already ill.

A stomach ulcer therefore is not just something that is happening to you, you are happening to it. Your fears, your jealousies, your hatreds, your inability to get on in life, can be (in some cases) just as harmful as germs or poisons—in fact, they act by setting free glandular poisons in your blood-stream. Scientists have discovered a reaction which they call the "stress response," and we now know that stress can ultimately lead to sickness or death without any bodily injury at all. Thus, Dr. L. J. Saul, a leading American doctor, writes: "Emotional stress in which there is no physical damage can produce responses which lead to actual damage and even to death." Rats in the laboratory can be killed through long exposure to fear caused by loud noises or other forms of shock without even being touched.

This stress factor is emphasised not because it is more important that the other enemies of the body or mind (it would be better to say body-mind), but because, as we shall see later, it does cause serious diseases, and, secondly, as mentioned already, it influences the process of recovery. A person who is afraid or has no hope is less likely to recover from pneumonia or another disease than one who is hopeful, who has peace of mind and confidence.

(2) **New Views about Health.** A great deal of nonsense has been talked about the healthy life; at one time we were told to take eighteen chews to each bite, to do deep breathing, to take plenty of exercise, to get lots of fresh air, to eat regularly (or to indulge in peculiar diets). But more recently,

eminent doctors have cast doubt on most of these fancies. Moderate exercise is necessary to health, but athletes who indulge in violent exercise have not always been noted for longevity. Fresh air is pleasant and stimulating, but, where actual breathing is concerned, it is no better than the air in most rooms. Certainly, one of the problems of our time is air pollution by smoke and Diesel fumes, which are highly dangerous, but at present we are considering ordinary fresh air in comparison with the air indoors, and, in this case, the experts say there is little difference so far as health is concerned.

A balanced diet containing correct amounts of the basic food substances is essential, but there is no evidence that when, or at what intervals, you eat makes the slightest difference—unless you are a sufferer from stomach ulcer, in which case it is necessary that the intervals between meals should not be too long. The whole business of having meals at fixed intervals is nothing but a social convention, and in modern life obviously a matter of convenience.

Sleep, too, is a necessity. But different people require vastly different amounts of sleep. Some manage on as little as three hours, others seem to believe that they need ten or more, and there are well-authenticated records of people who never sleep at all. For example, a certain Dr. Pavoni in Northern Italy did not sleep for sixty years and made a virtue of necessity by specialising in night calls! Insomnia is unpleasant, but its only harmful effect results not from sleeplessness itself but from worry about it; for many people seem to believe that if they do not sleep they will go mad or at least become seriously ill. This is quite untrue.

In a number of studies of men and women who lived to a ripe old age it was found that the only factors in common between them were that they had a good balanced diet of healthy food, that they had contented minds, and that they were interested in something which gave them an aim in life. They also came of long-lived families—for living a long and healthy life depends partly upon heredity.

So the main rules of health are: do not think too much about your health unless it gives you trouble; have an interest in life and be prepared to sacrifice a lot for it (nothing useful has ever been done by those who are always "taking care" and being over-cautious); eat a good balanced diet; do not worry, and have a contented mind.

(3) New Drugs. A great surgeon, the first of the moderns, was Ambrose Paré, who died in 1590, and one of his best known sayings was: "I apply the dressing, but God heals the wound." He was quite right; for until about forty years ago, or even less, all the physician could do was to put the patient in as favourable a state as possible to enable his body to cure itself. That is to say, there were hardly any specific drugs—drugs that had a direct effect on the disease. There was quinine, discovered by the Spaniards in America, which was specific for malaria, and there were iron (specific for anæmia) and digitalis (specific for certain types of heart disease), but otherwise nothing until the nineteenth century, when Paul Ehrlich discovered salvarsan, which is specific for syphilis. Ehrlich died in 1914, having conceived the brilliant idea of drugs which he described as "magic bullets"—*i.e.*, drugs which, like bullets, would be aimed at the real cause of the disease. They would, that is to say, be specific.

Since then a large number of such drugs have been discovered. For example, the antibiotics, such as penicillin, discovered in 1928 by Fleming at St. Mary's Hospital, Paddington. Later, Florey and Chain in Oxford, helped in the war years by the vast resources of the American pharmaceutical industry, were able to make penicillin available to the public in sufficient quantities by new techniques of production. Penicillin is practically non-poisonous (although it is possible to become allergic to it, sometimes with serious results). It can kill some germs in a d tion of one part of penicillin to one hundred mil parts of water; it is effective against streptocc the cause of blood-poisoning, sepsis in wounds, many other diseases: and also against the ge of anthrax, gonorrhœa, meningitis of some ty syphilis—a whole list of plagues which h troubled man for centuries. Blood-poison whether from wounds or childirth, used to almost incurable—now the rate of cure is 80 per cent.; anthrax and gonorrhœa have an alm 100 per cent. rate of cure. In pneumonia the is about 90 per cent., and early syphilis can cured in a week, instead of the previous two three years.

But this was only the beginning. Other a biotics—streptomycin, tetracycline, erythromy and many others—are helping to wipe out terrible scourges of the human race, in particu in the case of streptomycin, tuberculosis. sulpha group of drugs—sulphadiazine, sulp dimidine, etc.—have also proved a great b Then there are the new drugs which have creat a revolution in psychiatry—the tranquilli which relieve anxiety, the drugs which clear certain types of depression, and substances s as chlorpromazine which make it possible to n formerly violent patients in the wards of a gen hospital. The antihistamine drugs help in m cases of allergy, the anticoagulants prev further attacks of coronary thrombosis, and ev year new and powerful aids in the fight aga disease are discovered.

Of course, these potent new drugs are not w out their concomitant risks. The doctor trained to weigh the harm they can do against disadvantages of *not* using them in any partic case. He should not use them for every tri illness in which their only effect may be to sho slightly the course of a condition which, left al would recover of itself. Yet in Britain and o technically-advanced countries indiscrimi prescribing is common, largely because of p sure on the doctor from his patients and the d firms. The busy mother whose child has a r sore throat is not going to see the child swea out when she knows from past experience th dose of penicillin can remove the fever and m of the symptoms within twenty-four hours. is unlikely to listen to the argument that slower process is capable of increasing the bo resistance to future attacks, or that repeated ministration of penicillin may create germs w are insensitive to it in a future emergency. worse still, produce an allergy to the drug. thalidomide tragedy of 1962–3, when a new s tive, hailed as being both effective and safe (c were quoted of would-be suicides who had ta up to 100 of the tablets without loss of l resulted in the birth of children with undevelo arms and legs to mothers who had used the d in early pregnancy, and prolonged neuritis in s adults, has been quoted against the drug indu as an example of cut-throat competition allow new preparations on the market before they been exhaustively tested. But the truth is quite so simple. There can be no reason question that the drug industry needs to be u stricter control; that its methods of adverti its wares to the doctor are wasteful, importun and often in bad taste; that different firms out what is virtually the same drug under var trade names which merely leads to confus that the "authorities" quoted in the adverti of some drugs are often obscure individual countries not noted for the high standard of t practice of medicine writing in equally obs journals; and that many drug firms make gro initiated profits at the expense of our Nati Health Service. On the other hand, it mus remembered that some of the best drug firms h played a major part in medical progress. they must constantly check their comme instincts where these conflict (as they somet do) with your interests as the patient-consu To be fair about thalidomide, the fact is nobody previously had seriously considered possibility of a drug capable of causing defor in the unborn child, and, if they had done, quite likely that the danger would still have undiscovered, since only certain labora

mals respond to thalidomide in a similar way
man. The drug had been exhaustively tested
all ordinary methods before being put on the
rket, and for a number of years (during which,
Germany, it was on sale to the public without
escription because of its apparent safety),
illions of people took it without any ill-effects
her immediately or subsequently. Its terrible
e-effects were, in fact, limited to those mothers
o used it in early, not later, pregnancy, and in
lesser degree to a small proportion of adults
ho developed unpleasant, but not dangerous,
mptoms of neuritis.

The taking of any effective drug is always a
culated risk. We have mentioned that the
e of penicillin—a drug which is almost com-
tely non-poisonous—may nevertheless cause
er germs and fungi to multiply in the body
ch unpleasant results. This is because peni-
in wipes out, not only the disease-producing
rms it is being used to destroy, but the peni-
in-sensitive harmless germs which hold the
her potentially harmful germs at bay. Thus
se who keep on sucking penicillin lozenges for
real or imaginary sore throat may develop a
ck tongue due to the spread of a fungus nor-
lly present but kept under control. Other
tibiotics, described as "wide spectrum" be-
use they wipe out an even greater variety of
rms than penicillin, also kill the organisms re-
onsible for the absorption and possibly the
eation of vitamin B in the body, thus causing
vere vitamin deficiency. Tranquillisers made
various firms vary from the wholly useless to
e very useful, but both can have unpleasant
le-effects. One type is prone to lead in a small
mber of cases to severe depression, others may
ver the blood-pressure to a degree that causes
nting attacks, and serious blood and liver
seases are not unknown if not common. Both
nquillisers and the antihistamine drugs can
use some people to become extremely drowsy—
obvious danger if one drives a car or works on
ghts. Even aspirin causes gastric haemor-
ages which have sometimes been very severe
d even lethal, particularly in those with peptic
ceration of the stomach and duodenum.
spirin, one of the most useful and safest of drugs
ould never be taken for an "upset stomach"
by people with known stomach trouble. Such
tients should be warned that about 150 pre-
rations including some hang-over remedies
dely advertised for "upset stomach", contain
ge quantities of aspirin (acetyl salicylic acid).

None of this should deter the patient from being
vised by a doctor he trusts to use whatever
ugs are prescribed; it *should* deter him from
tting emotional pressure on his doctor to obtain
ugs unwillingly given. It is high time that we
ve up the notion that no patient should leave
e consulting-room without a prescription for
me pill or potion; for something like 40 per
nt. of patients simply require advice about the
nduct of their life from their diet to their relation-
ips with others rather than medicine of any kind.
he housing shortage, a bullying boss, or a nagging
other-in-law cannot be removed by a tranquil-
er—in fact, a tranquilliser, by making a man or
oman feel better, may prevent them from con-
ructively solving problems which exist in the
al world. We should all learn to rely as little
drugs as possible: stop taking tranquillisers or
p pills when we are merely worried about some-
ing that any normal person would worry about,
because we are just "fed-up"; stop using
tibiotics (which are badly needed elsewhere in
e world) for trivial infections in which they are
ybow useless; stop swallowing vitamin pills
hich do not relieve tiredness and are merely
sted on this overfed nation; stop buying any
tent medicine whatever. Modern drugs are
otent and effective; they are a dagger to destroy
e enemy of disease. But, like a dagger, those
ho play about with them incompetently and
nnecessarily are liable to get badly hurt.

(4) New Methods in Surgery. Only a few years
efore the Second World War many surgeons
ere saying that surgery had reached its extrem
mits. It was impossible, they believed, to improve on the delicate techniques then reached. But events have proved them wrong. Operations on the heart, for example, which would have been inconceivable a short time ago are now carried out daily—the heart can be opened and defects of the all-important valves made good. "Blue-Babies" or adults with a heart disease which might have led to their death in a few years are now cured by surgery, and it is possible during such operations to cut off all the blood from the heart by deflecting it through tubes to an artificial heart outside the body—a machine which pumps the blood round the body whilst the real heart is at rest.

This however, will be described in more detail later.

Then there are the new anæsthetics, such as Pentothal, which are injected into a vein in the arm instead of being breathed in through a mask, as were ether and chloroform or ethyl chloride. Pentothal is much safer, and avoids the unpleasant after-effects of vomiting and nausea, which usually followed the old type of anæsthetic. Most curious of all anæsthetists use the poison curare, used by South American Indians to poison their arrow-heads. Curare produces paralysis, but in small doses merely gives the degree of muscle relaxation which is so important to the surgeon when he is operating.

Lastly, we might mention the new techniques of plastic surgery. Thus large areas of skin which have been destroyed by severe burns can be replaced by shaving off thin layers from another part of the body. These do not need to cover completely the whole damaged area: small pieces are scattered over the wound and gradually grow together. Corneal disease (the cornea is part of the "window" of the eye, and when it becomes opaque the patient cannot see) is treated by removing the diseased cornea and replacing it by a cornea removed from a dead body, or sometimes from an eye which has had to be removed from a live patient for other reasons. There are, in fact "cornea banks" where corneas are kept in refrigeration for future use, just as there are "blood banks" for use in blood transfusions. Other advances in surgery will be described elsewhere in the section.

(5) New Approaches in Social Medicine. Medicine has passed through many phases from the time when disease was regarded as a punishment from the gods or a sign of devil possession to the present era, when increasingly there is a tendency to look on society as the patient. Indeed, one commonly hears doctors and sociologists nowadays talking about "the sick society."

The early primitive stage came to an end—at least in one part of the world—when in Greece, five centuries before Christ, Hippocrates and others began to teach that all diseases were due to natural causes. But after the first ray of hope the outlook began to deteriorate when, during the Middle and Dark Ages (that is, from the fall of the Roman Empire right up to the fifteenth century), there was a return to the belief in devil possession and supernatural causes.

Eighteenth-century medicine in Europe was materialistic, regarding the body as a machine. It was founded upon a sort of pseudo-science—although, of course, there were always individual exceptions, physicians such as Sydenham in England, who, avoiding all theories, based their work on observation of the patient. This mechanistic approach persisted right through the nineteenth century, but medicine became more and more truly scientific, and the century saw the most rapid advances in the field ever known until our own times: the discovery of germs by Pasteur, of antiseptics to combat them by Lister, of vaccination by Jenner and anæsthetics by the American Wells and the Scot Simpson. The use of the microscope by Virchow, who was a German, brought great advances in the understanding of disease and Ehrlich, another German, conceived, as we have already seen, the idea of "magic bullets" which would attack the germs at the

root of a disease without harming the patient. But one of the greatest of all these great men is perhaps the least known. His name was Edwin Chadwick.

From the earliest period of recorded history human communities had been constantly ravaged by great plagues which swept over their lands year after year, killing untold millions. Such plagues are recorded in the Bible and other ancient books, but, when town life became more and more common, as during the Roman Empire and the Middle Ages in Europe, the overcrowded conditions were even more favourable to the spread of disease. The Black Death of 1348–9 wiped out almost half the population of Europe. But, even in the first quarter of the nineteenth century in London, tens of thousands died from typhus, typhoid, and small-pox—and not only these, for periodically cholera would be brought into the country by travellers from abroad.

In the face of these terrible visitations the individual physician was helpless. He could not treat each one of the many sick even had he known how, and Chadwick's claim to fame rests on the fact that he was the first man to think in terms of *social* control of diseases, by so dealing with their causes that they were prevented from arising at all. In order to wipe out typhoid and cholera, he argued, we must ensure clean water supplies; for these diseases are caused by germs carried in polluted water. In order to attack typhus and plague, one must get rid of the flea which carry the germs of typhus and the rat-fleas which carry the germs of plague (including, of course, the rats, which, in turn, carry the fleas).

In the past, some attempts had been made to segregate the sick to prevent the spread of disease —for example, in the case of leprosy (which, strangely enough, we now know to be less infectious than most germ-borne diseases). But segregating those who are sick with typhoid or cholera is of little use if others are still drinking polluted water, just as it is of little use segregating plague cases if rats with their infected fleas are allowed to run at large. So these early attempts met with little success, due to lack of understanding of how the infections were passed on.

Chadwick was born in a Lancashire farmhouse where the children were washed every day all over, and he ruthlessly drove an obsession with cleanliness into the heads of his countrymen until, later in the century, it was possible for the German philosopher Treitschke to tell his class in Berlin: "The Englisc think soap is civilisation." Although this remark was meant cynically, there is little doubt that soap, if it is not civilisation in itself, has played a greater part in making civilisation possible than many more elaborate remedies. A population riddled with chronic infectious illness has neither the time nor the energy to apply to the arts or sciences, and soap did a great deal to reduce infection.

One of the first Public Health measures was introduced by Chadwick and others when they brought in legislation to purify the water supply of London. Previously, the citizens had used water from the Thames (they still do, but only after it has been filtered and sterilised at the waterworks!), and from filthy, refuse-laden ponds and springs. Later, Chadwick helped to found the Poor Law Commission, and produced a Report in 1842, the principal suggestions of which were: a municipal water supply for all towns; scientific drainage both in town and country; and an independent health service with large powers for dealing with those who endangered the lives of others by polluting water or causing nuisances. He also proposed a national service for interment of the dead; for in those days bodies often remained for days in the overcrowded homes of the poor without burial.

What has the twentieth century contributed to the concept of social health? Well, of course, there has been a great deal of legislation along the lines initiated by Chadwick to control disease, and a great many other measures have been introduced concerned with the idea of positive health—not merely preventing bad health, but trying to b about the highest possible state of good he Orange juice, milk, and good meals for sch children have brought about a transformatio child health which has become apparent to least observant in the last ten or fifteen ye And the National Health Service is in the di line of descent from early nineteenth-cen legislation.

But in future years it is probable that the m achievement of the twentieth century in so medicine will prove to be its extension of the t "social health" to cover every aspect of c munity life, not only in such subjects as bo health and its control of social means, but such problems as mental illness, crime, d quency, drug addiction, and so on. What we now asking ourselves is: how far are t problems produced by society itself, and if th the case, how far can we go in preventing t by social means?

Social medicine takes the view that t problems can never be dealt with solely by me lising and retribution, but only by dispassiona analysing causes and dealing with them. this century we have developed a social science. Not always, it is true, a very informed social conscience, but at least this good beginning. There are organisations dealing scientifically with delinquency, for de with problem children, for spreading knowl about cancer in order to show people that it be successfully treated if taken in time. organisation known as "Alcoholics Anonymo has, on the whole, been more successful in trea alcoholics by social means than have any of individual medical methods. Mental illnes also treated by group methods, which, toge with the new drugs, have revolutionised position in mental hospitals. We can well with John Donne, who died in 1631, that "no is an island . . . every man's death diminis me; for I am involved in mankind." This is attitude of twentieth-century social medicine.

Summary. Perhaps we can sum up our gress in the past hundred years more dramatic in terms of hard facts.

One hundred years ago, a surgical operation never undertaken except under the gravest cumstances. There were no anaesthetics an antiseptics, and the operation was carried ou a surgeon in a filthy tail-coat, stained with congealed blood of countless operations (in the surgeons of that time took pride in the c condition of their coat as showing how m experience they had previously had). Germs the part they play in producing disease were known, and Paul Ehrlich had not yet been b so there were no "magic bullets" to at syphilis, or sera for diphtheria and other dise The mentally ill were simply locked up with treatment and subjected to such indignities a strait-jacket and the padded cell; now they given treatment which becomes more effec each year, the padded cell and strait-jacket gone, and in the more progressive hospitals the ward doors are not locked.

Only thirty years ago you would very li have died if you had developed pneum "childbed fever" after the birth of a c meningitis, dysentery, typhoid, or tubercu With such infections as blood-poisoning would have had practically no chance at Today, the sulpha drugs and the antibiotics h changed all that. Syphilis and gonorrhœa lifelong tragedies both to the patient and family, but now they, too, can be conquered.

The National Health Service has brought possibility of good treatment equally to all, other bodies—some of them privately run— with alcoholism and neurosis, with rehabilita of the mentally and physically ill, with spas birth control, and marriage guidance. It i to us to see that all these facilities are used t full by all who need them.

PART II. DISEASES ARRANGED ACCORDING EITHER TO THEIR CAUSE OR THE AREA OF THE BODY AFFECTED.

THE INFECTIOUS DISEASES
INTRODUCTION.

FECTIOUS diseases are those which are caused by
invasion of the body by organisms from outside
e word "organism" simply means other living
ngs, and we are using this word because, as will
seen later, it is not only what are known as
erms" which can cause infection). We know,
), that what is generally typical about this
oup is: (*a*) that the disease can be passed on
m one person to another, and (*b*) that it is
ually accompanied by a raised temperature or
ver. Now (*a*), of course, is always true, because
e definition of an infectious disease is one that
n be passed on to others, but (*b*) is not always
ue, because a few infections produce little or no
mperature, and also because it is possible to
ve a raised temperature (again in only a few
ses) without any infection. For example,
rtain types of brain injury, tumour, or hæmor-
age can produce a raised—or lowered—tempera-
re, and so can the injection of some foreign
bstance such as milk into the muscles. This
known as "protein shock," and was at one
ne used in the treatment of certain illnesses.
nally, solutions of dead germs, such as the anti-
phoid vaccine given to protect troops during
e War, may lead when injected to very high
nperatures. But, by and large, we are entitled
suppose that the patient with a raised tempera-
re is probably suffering from an infection.

ypes of Infection.

As we have seen, it is not only germs which
use infections—so from now on we shall give
rms their proper name of "bacteria." Here is
list of the chief offenders which are liable to
tack our bodies: bacteria, spirochætes, viruses,
ngi, amœbæ, worms and other parasites. Of
ese, bacteria and viruses are by far the most im-
rtant, but let us look at them all more closely.

Bacteria are tiny living things which can be seen
ly under a fairly powerful microscope. Some
e grouped like bunches of grapes (staphylococci)
in strings or chains (streptococci). They are
ven these names because "staphylos" is the
eek word for a bunch of grapes, and "streptos"
eans a chain. Yet others are comma-shaped
ich as the cholera vibrio), or shaped like a
umstick—a rod with a small knob at the end
he tetanus bacillus, which causes lockjaw).
It would be a mistake to think that all bacteria
e harmful; for without some species we could
t survive for long. Bacteriologists divide them
cording to their behaviour in the human body
to three groups: saprophytic, parasitic or
thogenic, and symbiotic. The *saprophytic*
ganisms are bacteria normally found in the
in, mouth, and intestines; they do us neither
arm nor good. The *parasitic*, or as they are
ore usually called, pathogenic (*i.e.*, disease-
oducing) organisms, are the harmful ones with
hich we are naturally more concerned. Lastly,
ere are the *symbiotic* organisms, which, whilst
king something from the body, give something
return. For example, cattle would not be able
digest the cellulose of the grass they eat were
not for helpful bacteria in the lower parts of the
testines, and there are certain bacteria in the
rge intestine of man which build up vitamin B2.
Bacteria have two peculiar characteristics:
ch reproduces by splitting into two separate
dividuals as often as every twenty minutes in
vourable circumstances like an open wound.
no bacterium were destroyed, one individual
uld produce a mass of bacteria larger than the
hole world in a matter of a few weeks (since each
the offspring also divides into two, which in
rn divide again—the progression goes: one
ves birth to two, these two to four, the four to
ght, eight to sixteen, sixteen to thirty-two, and
on—you will see, if you work it out, that in a
ort period the figure becomes astronomical).
ortunately, many bacteria have accidents, so for
e present the world is safe! The other curious
ing about bacteria is that, barring accidents,
ey are potentially immortal. Under ideal conditions in which no bacteria were killed, none would die; for a bacterium there is no death from old age, no corpse except when it is actively destroyed. It simply goes on dividing, dividing, and subdividing for ever.

How, then, are bacteria destroyed? Briefly, the answer is that most are destroyed by the natural defences of the body of whatever host they are preying on; others are destroyed by antiseptics and the new drugs; and many are destroyed when they are excreted from the body in the sputum or through the bowels and land in places where they are dried up and cannot survive—although some bacteria in such circumstances can form what are called "spores," rather like the seed of plants, so making it possible for them to survive in a state of suspended animation for months on end until picked up accidentally by another unfortunate host. Finally, bacteria, in addition to all these possibilities, face another danger: they may themselves develop disease. This disease is caused by even more minute organisms known as bacteriophages (viruses which affect bacteria), discovered by the French bacteriologist d'Hérelle a good many years ago. Attack by bacteriophage causes whole groups of bacteria (known as "colonies") to disintegrate and become harmless.

Although bacteriophage has been used in the treatment of some diseases in human beings, this method has now been largely given up, since the new drugs are infinitely more effective.

Spirochætes. Spirochætes, like bacteria, are minute organisms, but differ in being shaped somewhat like a corkscrew and in being able to move (which many bacteria cannot do). Their progress is produced by a sideways wriggling motion. The two main diseases caused by spirochætes are syphilis and spirochætal jaundice. Spirochætal jaundice is carried by rats, and is common in those who work in mines. It is now rare in Britain, but still occurs in Japan, Egypt, and Malaya; the infection is passed through the skin where the excreta of infected rats mingles with water on damp ground in the mine where miners kneel. Infection may also occur through eating infected food.

Viruses. Unlike bacteria, viruses are too small to be seen under an ordinary microscope. They can, however, be photographed in some cases under an electron microscope, which uses a magnetic field instead of a glass lens and a stream of electrons in place of a beam of light. Viruses cause such diseases as typhus, measles, mumps, poliomyelitis, smallpox, and chickenpox—not to mention such plant and animal diseases as tobacco mosaic disease and foot-and-mouth disease, which often have serious economic consequences. Other virus diseases are psittacosis (an infection of parrots and similar birds which can be transmitted to Man), swine fever in pigs, influenza in Man, and myxomatosis in rabbits. They also cause, it is believed, the common cold.

The main characteristics of viruses are, first, that they can only grow in living cells—unlike bacteria, which readily grow in the laboratory on plates containing a jelly made from meat broth, gelatin, milk, and other delicacies. The scientist, therefore, must keep them in portions of living tissue kept alive outside the body. Secondly, they are so small that they pass through the pores of the finest filter. Thirdly, a first attack usually produces immunity for life. Second attacks of the common virus diseases mentioned above are very rare; but unfortunately, this rule does not apply to influenza or the common cold. Fourthly, there is reason to believe that viruses represent an extraordinary intermediate stage between the living and non-living; they can, for instance, be produced in crystalline form and yet are just as dangerous when "thawed out." Lastly, the virus diseases have proved for the most part to be little affected by the new antibiotics and other drugs, although vaccination in smallpox and the injection of sera from infected patients in other infections may give immunity for longer or shorter periods.

The two great practical problems that doctors face with viruses are: (i) many viruses are unknown because of the difficulty of growing them outside the body in suitable tissue culture. They cannot therefore be conveniently identified in specimens from the patient, as bacteria can; and (ii) they are unaffected by antibiotics like penicillin. It has been a great step forward to grow viruses artificially in tissue culture, in which they are identified indirectly by the effects they have on the cultured *cells*. But since we do not know exactly how to grow some viruses (like those of infective hepatitis) they have still not been seen.

When we recover from a viral illness like chickenpox, we probably do so by producing virus-killing substances inside our own cells. Scientists are currently searching for these substances in case they can be used, like penicillin, to cure viral disease.

Fungi. Some infections are caused by fungi—that is to say organisms belonging to the same group as moulds, mushrooms, and toadstools. Penicillin and some other antibiotics are produced from moulds, so, as in the case of bacteria, some fungi are helpful; they even help to destroy each other, as bacteria do. For example actinomyces, which can cause infection of the jaw and other tissues, is destroyed by other tissues.

Most fungal infections are trivial and limited to the skin. But, although trivial, they can be unsightly and uncomfortable. Ringworm of the scalp, dhobie itch—an infection of the groin spread by infected underclothing—and so-called "athlete's foot" are caused by a fungus.

Amœbae. Amœbæ are small, single-cell organisms, the largest of which (a harmless type found in stagnant ponds in Britain and elsewhere) is just visible to the naked eye. It is about the size of the head of a pin. Amœbæ move, in the species which are capable of moving, by pushing forward a part of the cell in the appropriate direction and causing the rest to flow into the advancing portion. Like bacteria, they reproduce by dividing into halves, each of which becomes a new amœba.

The main human disease caused by amœbæ is amœbic dysentery (not to be confused with bacillary dysentery).

Parasites. These may live on the skin like lice (which can carry typhus) or fleas (carriers of plague), or the parasites of scabies which burrow into the skin, or they may live part of their time in the blood or other tissues, like malaria. They often have complicated life-cycles involving other hosts (like mosquitoes) at certain stages of development.

Worms. Worms are intestinal parasites, but the only common types found in Britain are threadworms, the tiny thread-like worms which cause irritability and itching in the skin of children, less often in adults; round-worms, somewhat resembling the ordinary garden earthworm, which seldom lead to symptoms; and tapeworms, which may reach a length of 10 or even 20 ft. Many parasitic worms (like parasites elsewhere) lead a double life—they spend part of their life in the human intestine and the other part in the muscles of another animal. The tapeworm, for example, whilst in the human intestine, lays eggs which pass out of the body in the excreta, and are then swallowed by pigs, especially in those parts of the world where human excreta are used as manure in the fields. In the pig, the eggs form cysts in the muscles—meat infected in this way is known as "measly pork"—and when, in turn, the meat is eaten by man, the process in the intestine begins all over again.

Less common types, from our point of view, are the Russian tape-worm (which, as befits a Russian, grows to nearly 30 ft.!); this type is spread by caviare or undercooked infected fish. The small, leaf-shaped liver fluke, lays eggs which are passed into canals or pools in tropical countries in the urine of infected people, hatch out and enter a water snail, and finally leave the snail in the form of small parasites which pierce the skin of bathers, whence they pass to the liver and subsequently the bladder and rectum. This is a serious condition, as is also filariasis (another tropical disease), for which, unlike bilhar caused by the liver fluke—no cure is known. tropical disease known as loa-loa is caused variety of filaria.

How the Infection is Spread.

Infection is spread in many ways, some of w have already been mentioned. In the com fevers found in Europe and elsewhere one o most frequent ways is by *droplet infection*—th to say, by minute drops carrying the germs w are coughed or sneezed into the air by som already suffering from the disease. Such d lets can be projected into the air for 10 f more, and when breathed in by someone wi range infection may result. Next commo mode of spread is perhaps by *infected food*, a and the dirty hands of those who prepare f cholera, dysentery, food-poisoning, and typ are spread in this way. Spread by *direct co* is found in the venereal diseases (usually, bu always, spread by sexual intercourse with som who already has the disease), and, of course, fleas, and other parasites, including the sc mite, are spread by contact with the infe individual—or sometimes with his clothes or linen. Spread through an *intermediary* whether it be lice, fleas, or mosquitoes carr infection, or the various means adopted by wo has already been described above, so no more be said. Lastly, the infection may result *bacteria already within the body*; for example bacillus coli which lives in the large intesti there harmless, but if it gets into the bladd the ureters (the tubes leading from kidne bladder) a quite unpleasant result may follo the form of cystitis or pyelitis.

How the Body Deals with Infection.

The body has many mechanisms of def against intruders, but suffice it to say here there are two main ones. First, substa known as antibodies and antitoxins are prod in the blood—the antitoxins to neutralise poisons produced by the invaders, the antibo to render them helpless, for example, by ca them to clump together so that they can r easily be dealt with by the second defence mec ism. This second mechanism is provided by white cells in the blood, some of which phagocytes) act like amœbæ and swallow up destroy the germs. Antibodies and antito can be transferred from one individual to anc and are used in medicine both to prevent fection and to cure it. This is known as munisation, and can be active or passive. A immunisation is produced by injecting eith solution of dead bacteria, as in the case of typhoid injections, or by injecting live, weakened, strains of the organism, as in the of smallpox vaccination. In both cases the b is stimulated to produce its own immune stances. Passive immunisation is used eithe people who have been in recent contact infection or who are already ill, and in this the antitoxins produced in another person wh had the illness are injected in the form of seru i.e., the liquid part of the blood without the b cells. All these natural defences are ineffi in the ill, the underfed, the very young, and very old.

Antiseptics.

We have already discussed the other wa which bacteria are destroyed and now need make brief mention of antiseptics, and antibio The earliest antiseptic was carbolic acid, use Lister in his operating-theatre in the form fine spray directed throughout the operatio the wound, or sometimes in the form of s from a kettle containing a solution of carb But carbolic is dangerous, and since Lister's many more useful antiseptics have been covered. Acriflavine, thymol, and other favourites have been discarded too. The va forms of carbolic are still used to disinfect dr but, to tell the truth, the use of antise nowadays is very limited. In surgery *antiseptic* method has given way to the *as* method—instead of fighting sepsis we see t

t no possibility of sepsis is present before erating: all instruments, the surgeons' and ses' hands, the skin, are sterilised—the truments by boiling, the dressings by dry heat, hands by soap and water, and almost the only tiseptic used is to clean the patient's skin in area to be operated on.

Antiseptics are used as first-aid treatment for s and wounds, but should be applied only once a general rule—that is, when the wound is st received. The trouble with antiseptics is at as well as killing germs they also kill the rrounding tissues, which antibiotics never do. Antiseptic sprays to purify the air of a room or destroy germs lurking in the dust on the sick-om floor—or any other floor—are practically eless. To quote the *British Medical Journal*: There is no good scientific evidence that any of e chemical air-disinfectants can control the read of infection in places such as schools, ices, or cinemas. Nor is there good evidence at any substantial effect on the spread of illness n be obtained by disinfection of dust."

Neither is there any good reason to believe that outh-washes and gargles have any effect other an making the mouth feel fresher and (temrarily) removing mouth odour—by covering it with the scent of the antiseptic. Mouthshes are in contact with the bacteria for far o short a time to have any damaging result, d, in the case of tonsillitis and other diseases, t the important bacteria are hidden far out of any nger from gargles.

ntibiotics.

The antibiotics—penicillin, streptomycin, eryromycin, terramycin, aureomycin, and chloramenicol—have already been dealt with, and only vo important practical points need to be menioned. These are that although most of such ugs are entirely safe under ordinary conditions, is extremely dangerous for the layman to use em without medical guidance. If, for example, eople get into the undesirable habit of sucking enicillin lozenges for sore throat and keep on oing this every time the sore throat returns, they ay become sensitised to penicillin so that, when ey become really ill—say, with pneumonia—the rious illness no longer responds to the drug. Or e same habit may make them allergic or hyperensitive to penicillin, and an injection given ter may have serious and even fatal results.

Doctors no longer use the lozenges anyway, ecause of this danger and another one which is nat excessive use of antibiotics may kill not only he dangerous bacteria, but also the ones which re helpful to the body. When this happens, ther types of organism which are not affected by ntibiotics will multiply in the absence of the acteria which normally keep them under control. hus chloramphenicol or aureomycin, by killing seful germs in the large intestine, may cause itamin B deficiency, and when the non-sensitive rganisms have their natural enemies removed hey may step in and multiply, causing inflammaion of the mouth, diarrhœa, and occasionally a atal bowel infection. Chloramphenicol is too angerous for general use.

ieneral Treatment of Fevers.

Fevers are ordinarily heralded in by a rise in emperature which is noticeable either by a flushed ace or by alternate sensations of heat and cold. A patient with a high temperature may have hivering attacks known as "rigors." Tell the doctor.

A high temperature does not necessarily (especially in a child) mean that the trouble is serious but the lay person should always treat it as such nd certainly call a doctor if the patient is a child r an elderly person.

Even the trained physician finds it difficult to ell one fever from another in the early days; for nost of the common fevers begin in more or less he same way. It is only when a rash or some other more definite sign becomes evident that a certain diagnosis can be made, and these may not show themselves until the patient has been feeling " run-down " and fevered for some days. Incidentally, although a clinical thermometer is very useful thing when properly used, many a doctor must feel that, in unskilled hands, it is a menace. The " fussy " type of mother who is constantly taking her child's temperature whenever it looks in the slightest degree different from usual (probably it is simply feeling justifiably bored with its parents), not only causes anxiety to herself but also gives the habit of anxiety to her child. The child is made to feel that the world is a dangerous place, full of germs and all sorts of causes for fear—as indeed it is, but one needs a sense of proportion, and other dangers which we think much less about are at least as frightening and twice as deadly as most germs. Whatever you do, don't get the thermometer habit; your child, so far as fevers are concerned, is a good deal tougher than you.

Briefly, then, the way to treat a fever in the early stages before the doctor comes, and before one knows exactly what is wrong, is as follows:

(1) Put the patient to bed.

(2) Give little, and easily digested, food; if the patient wants none, give none.

(3) Give plenty to drink—the proprietary preparations containing lemonade and glucose are excellent, but water, weak tea with sugar, or home-made lemonade with squeezed-out lemon juice and sugar, whichever the patient likes best, are at least as good.

(4) Aspirin is useful to relieve headache or other pains and will reduce fever for two or three hours. But it will cure nothing. The patient will be more comfortable, but his illness will not be cured by aspirin except in certain very special cases. Soluble aspirin is best. Do not have special children's aspirins in the house. They are often nicely flavoured, the children are tempted to eat them like sweets, and there have been serious cases of poisoning. For small children, use suitably small quantities of ordinary adult soluble aspirin, having checked the dose with your doctor. Other methods of cooling seriously fevered patients such as bathing, tepid sponging, etc., are strictly for the doctor to prescribe. A patient as hot as that should be in a doctor's hands anyway.

THE INFECTIOUS FEVERS.

The remarks made above apply to the management of *any* fever, and we are now going to discuss particular infectious diseases, beginning with the common childhood fevers, then passing on to less common ones, tropical diseases, and worm and parasitic infestations.

The common infectious fevers are caused by bacteria or viruses, and it is useful to know the meaning of the following terms: *incubation period* is the time which elapses between being infected and developing symptoms; *prodromal period* is the time which elapses between the end of the incubation period and the appearance of a rash; *quarantine period*, the maximum time during which a person who has been in contact with the infection may develop the disease—this is usually two days more than the incubation period; *isolation period*, the time a patient is supposed to be isolated.

Views regarding the common infectious fevers have changed a good deal in recent years. Disinfection of rooms is now regarded as almost useless, and more cases are treated at home. Quarantine in the case of the common fevers is thought by a good many doctors to be a waste of time, since all it can do is to postpone infection from early childhood to early adult life, when it is likely to be more serious. For it is a characteristic of these fevers that they affect the adult much more violently than they do the child. However, on this, and all other points, you will have to be guided by the opinion of your family doctor.

Virus Diseases.

First, we shall take the common virus diseases, measles, chickenpox, and rubella or German

measles, then the other virus diseases, mumps, infective hepatitis, virus pneumonia, and some less common conditions which do not always produce a typical rash as in the case of the first three.

In nearly all of these fevers there is a long incubation period, and one infection gives immunity for life.

Measles. The incubation period is 10–11 days. The first sign is the appearance of symptoms rather like a severe cold. The eyes become red, and exposure to light is unpleasant, the nose runs, the throat becomes inflamed, and a dry, harsh cough develops. There may be headache, and the temperature rises to 102° or more. Usually the patient is a child, and especially typical is the development of so-called Koplik's spots, which are small, bluish-white, raised spots seen on the inside of the cheek at the back of the mouth. The rash begins on the fourth day of the prodomal period, *i.e.*, 14 days after the initial infection. It shows on the forehead and behind the ears, spreading within a day downwards over the whole body; in another two days it starts to disappear, but often leaves behind a sort of brownish staining which may last for one to two weeks.

Measles can be serious, especially in very young children because of its complications, such as bronchopneumonia and infection of the ear, which can now be treated with antibiotics. These drugs have no effect on the measles virus, but only on the secondarily invading bacteria which have invaded the lungs and ear during the illness. The illness can be attenuated or lessened by injection of antibodies (gamma globulin) from an immune adult, and this is often worth while in the very young.

Rubella or German Measles. Incubation period 14–19 days. A mild fever, similar to measles except that the rash is usually the first sign that anything is wrong, and the temperature is rarely above 100°. The eyes may be pink, and there are enlarged glands at the back of the neck. The rash disappears completely in thirty-six hours. There are no complications.

German measles, in itself, is harmless, but if a woman gets the disease in the early months of pregnancy malformations in the child may appear at birth. Hence some doctors believe that girls particularly should have the opportunity of contracting German measles before they grow up. There is no special treatment, except the general rules for fevers given above.

Chickenpox. Incubation period 14–15 days, but may be more variable. In children chickenpox is a mild fever which begins with the appearance of tiny blisters on the chest and back. These later spread outwards to the legs, arms and face, and cause itching. Treatment is the general one for fevers already described. Calamine lotion or dusting powder will be helpful for the irritation, and the child's nails should be cut short to prevent scratching and infection of the spots. Whereas children are usually little bothered by chickenpox, young adults may be much more drastically affected—a temperature of 104° is not uncommon, and there may be severe headache.

Mumps. Incubation period 17–18 days. Everyone knows the typical appearance of the patient with mumps—the swelling in the salivary glands in front of the ears which makes the face look full. This causes pain later on, and it may be difficult to open the mouth. Temperature is not usually high (about 101°). Although uncomfortable, mumps is rarely dangerous, but orchitis—swelling of the testicles—is sometimes a complication. Fluid diet should be given if eating is painful, with mouth-washes, and rest in bed.

Infective Hepatitis. "Hepatitis" means inflammation of the liver, and infective hepatitis, which is much the commonest cause of jaundice in young adults, is a virus infection of the liver. In fact, this disease caused serious difficulties during the Italian campaign of 1943, and has probably become more frequent (or, at any rate, more frequently recognised) in this country since War. The main symptoms are fever, followe jaundice, which is first noticed in the white the eyes as yellow staining, then in the skin. urine becomes coloured also, and this is easily noticed if, on shaking in a bottle, the f shows coloration. If the froth remains white jaundice is present. Treatment is a matter the doctor, but great care should be taken, by the patient and those in contact with hi wash the hands thoroughly after urinating defecating, after handling utensils from the Normal, and both before and after eating; for disease is very infectious.

Virus Pneumonia. Pneumonia is us caused by bacteria, and when we speak of p monia, that is the type we ordinarily refer Virus pneumonia is known by doctors as "p monitis," and is believed to be closely relate influenza. There is no specific treatment so and since diagnosis is a specialist matter, more need be said except that the symptom general resemble those of ordinary pneumo Psittacosis, another virus disease, can also to pneumonia, and although there is no spe treatment for virus infections of the lungs, always worth while trying the antibiotics or su drugs in view of the possibility that the condition may be caused by a secondary inva by bacteria.

Influenza. While serious epidemics of fluenza take the form of a very dramatic and fatal disease—for example, the epidemic "Spanish 'flu" which followed the First W War killed more people than the actual fighti the milder type more usually seen is difficul distinguish from the common cold. In many people who complain of "a dose of 'flu" are suffering from simple colds.

However, a sudden onset, aching in the mu of the back and legs, and redness of the would suggest influenza, and especially typic the depression and weakness which follow fluenza but not a cold. The measures sugge above for the general treatment of fever shoul applied; but the depression and weakness w follow influenza may need special treatmen the doctor.

Colds. Although everyone thinks he, or knows what a "cold" is, the issue is not so sim for the symptoms of fever, running nose, a run-down, "headachy" feeling are found many illnesses. They may be observed, as have seen, in the early stages of measles b the arrival of the rash, or in a number of fevers, such as whooping cough. Mild attac influenza (see above) may resemble the com cold, and blocking of the nose with discharge fever may be due to sinusitis—although here t is usually pain above, between, or below the Colds can be caused by any one of thirty diffe viruses known as "rhinoviruses" as well a others which cause influenza, or infect gl (adenoviruses). This is why a single cold not confer immunity on the sufferer. I probable that you will not catch a cold from same virus, at least for the rest of the year, there are all those others waiting to infect with other colds in buses, tubes, and c crowded places. Like all infections, do not fo that the best way to avoid them is to generally well, and in a good nutritional s Do not spend money on injections or c vaccines. They do not work, probably bec of the multiplicity of viruses involved. It is unlikely that added vitamins or other exper additions to the normal diet will do any goo all provided you are eating sensibly. There recently been a vogue for treating colds massive doses of Vitamin C. This doesn't either, as has recently been proved.

Poliomyelitis. "Polio," or infantile para as it used to be called, is a virus infection o motor nerves—the nerves of movement—at point where they leave the spinal cord. tunately, all the nerves are never affected, only a few controlling one or more muscle gro

these groups happen to be the ones controlling eathing or swallowing (which, fortunately, is t very common) the results may be serious, but linarily the muscles affected are those of the s or arms. Poliomyelitis is almost as common w in adults as in children. Usually it occurs small epidemics after hot weather, that is in mmer or Autumn, and it often seems to strike fairly healthy normal people. This, however, not because healthy people are specially prone such, but because those living under less gienic conditions are more likely to have deloped immunity. In point of fact, the majority cases of polio are so mild that they are never scovered at all, and paralysis does not develop; ch people are specially dangerous, precisely cause they pass unnoticed and spread the disease others.

Like many other infections, polio begins with re throat, fever, and sometimes vomiting five to n days after contact. There may be severe adache and rigidity of the neck muscles. aralysis is noted about the second or third day ter this, and is usually at its maximum from the art, although this is not always the case. This age lasts two or three weeks, by which time the mperature is down and the paralysis greatly nproved, although further improvement may go up to eighteen months after the acute stage.

This is another disease which has been draatically reduced and even wiped out in many eas by the widespread use of vaccine. However, when the illness is already present attention directed to relief of discomfort, resting and olinting the affected limbs, and preventing read of infection to others. The Kenny ethod, devised by Nurse Kenny, and much ublicised as a means of reducing permanent aralysis, is not believed by most doctors to be ny improvement upon orthodox methods. The e of the iron lung is restricted to cases where the uscles controlling breathing are attacked, and ny permanent paralysis of the limbs can often e helped by surgical operation.

Encephalitis. This is an infection of the brain aused by a virus, first noted in Vienna in 1916. here was an epidemic in London in 1918, but it not very common today.

Smallpox. Smallpox was once common in Western Europe, and, as late as the early nineenth century, was not unknown in Britain. low, since the introduction of vaccination, it is omparatively rare in industrialised countries, ithough minor epidemics have occurred here ecently. Jenner, who introduced vaccination, oted that dairy-maids who had suffered from the ild disease known as "cow-pox," contracted rom the udders of infected cows, and transmitted o the hand of the dairy-maid, did not develop malipox. In fact, cow-pox is a mild form of malipox modified by transmission through cattle. Vaccination should be carried out at the age of hree months, and repeated at the ages of seven, ourteen, and twenty-one years—also at any time hen an epidemic occurs, or when travelling to ny part of the world where smallpox is prevalent, r where immigration laws stipulate that it must e done. Many countries insist on an international certificate of recent vaccination before anding. Your family doctor will make out the ertificate (he is entitled to charge you for it) and our local Medical Officer of Health will countersign it. Smallpox is one of the diseases which can ery readily be spread from countries where it is prevalent because of the great increase in numbers f people travelling about the world by air.

Smallpox attacks people of all ages and is arried by excreta and droplet infection, but articularly by the dried scales on the skins of onvalescent patients; it is now most common in he tropics.

Smallpox is similar in many ways to chickenpox. Typical cases are easy for the qualified doctor to listinguish from one another, but one of the difficulties of vaccination (as with Typhoid, and other artificially conferred immunities) is that the typical signs are often modified. Differential diagnosis is a job for the expert, and if your own doctor is in any doubt, he will consult with the local health authorities. The disease begins with shivering, headache, and backache, and the temperature is raised to 102–104°. On the third day a rash appears, which turns into small blisters on the sixth day, and the blisters become filled with pus by the ninth day. On the twelfth day they burst and form crusts. Unlike chickenpox, in which the rash starts in the middle of the body and works towards the outer parts, smallpox produces a rash which begins in the scalp, forehead, wrists, and feet and then moves towards the middle.

Smallpox is a serious disease, and the result depends largely upon whether the patient has been vaccinated within seven years of the attack. Contacts should be vaccinated and kept under observation for sixteen days; the patient must be isolated until all the scabs have separated and the skin healed. An effective drug has recently been announced.

Glandular Fever. This is sometimes called infective mononucleosis, since one of its features is an increase in certain mononuclear white cells and an alteration in their appearance. Another feature is an apparent infectivity. Beyond this the disease is a great mystery, and although it is probably caused by a virus, it may even be related to other (malignant) diseases of white cells. This one, however, is not dangerous although it often causes a lot of trouble by dragging on for many weeks. The main symptoms are fever, enlargement of lymph glands and sore throat. The patient feels very debilitated and often very depressed. Diagnosis is often very difficult, but there is a blood test known as the "Paul-Bunnell" test which is almost specific for the disease. The patient is usually presented as a case known to doctors as "P.U.O.," meaning Pyrexia (fever) of Unknown Origin. He has often been treated with several antibiotics, one after another, without effect, because the causal agent is not affected by these drugs. He is only very mildly infective, and it is unusual to insist on isolation or quarantine.

Typhus. This disease used to be known as "jail fever," because it was frequent in prisons; but overcrowding, poverty, and bad hygienic surroundings anywhere are suitable conditions for epidemics of typhus. Improved conditions in industrialised countries have made it unusual, since typhus is carried by a virus carried from one person to another by lice, and where lice are absent the virus is powerless to enter the human body.

Typhus comes on suddenly with a rise in temperature of about 102°, but within four days it may be as high as 107°. There may, or may not, be a rash at this time, and in the second week, when the temperature is at its highest, there is delirium, weakness, and a feeble pulse. The typical typhus rash appears about the fifth day as reddish blotches on the chest, abdomen, and wrists.

Typhus is, needless to say, very serious but responds to such modern antibiotics as chloramphenicol, aureomycin, and terramycin. Preventive measures are directed towards destroying all lice with D.D.T.

Rabies. Finally, we shall deal very briefly with a number of less common virus diseases, beginning, as is appropriate, with *hydrophobia or rabies*, since it was in this infection that the great French scientist Louis Pasteur (1822–95) showed the possibility of prevention by vaccination. Unlike Jenner, with his ready-made cowpox virus, which we have seen to be the virus of smallpox weakened by natural passage through cows, Pasteur had to weaken the rabies virus by passing it through rabbits. The rabbits were infected, and after death the spinal cord was dried and powdered, a solution passed through another rabbit, and so on until the virus was sufficiently weakened.

Rabies is spread by the bite of infected animals, usually dogs, cats, or wolves, who are driven mad by the disease; in Trinidad, however, it has been spread by vampire bats. Those who are bitten usually show no symptoms for six weeks or more,

but sooner or later convulsions and delirium arise, which within four to five days are fatal.

There is no cure once the symptoms have developed, but Pasteur's serum, if given soon after the bite, prevents illness in the vast majority of cases—the sooner after the bite, the better the outlook. Dogs should be muzzled in areas where the disease is common, but quarantining imported dogs has made the infection almost unknown here.

Psittacosis. This is another virus disease which is of interest mainly in that it is spread by birds of the parrot group, such as parrots, love-birds, macaws, and the rest. It occasionally occurs here in people who have been in contact with birds of this type, and is serious both to the bird and its owner. As in the case of rabies, quarantine regulations have greatly reduced the likelihood of infection in Britain.

The symptoms of psittacosis are fever, cough, and bronchitis. The disease is especially dangerous to old people, but it responds to the same antibiotics as typhus.

Sandfly Fever, or phlebotomus fever, *Dengue*, or breakbone fever, and *Trench Fever* are all somewhat similar conditions in that they resemble influenza and are rarely fatal. They are all due to viruses, spread in the first case by sandflies in tropical climates; in the second by mosquitoes in tropical climates; and in the third by lice in temperate climates. They are all typical "soldiers' diseases"; the first two were common in the Middle East and Far East during the last War, the third during the First World War in France.

Yellow Fever. Of all the virus diseases, only four can be prevented by vaccination—smallpox, hydrophobia, yellow fever, and poliomyelitis. Yellow fever is carried by a mosquito known as Stegomyia, common in South and Central America and in African ports. For its spread, it therefore needs: a hot climate, the stegomyia mosquito, and an infected person.

In 1898 the United States was at war with Spain in Central America, where yellow fever was a serious problem. Following this war the United States, by this time acutely aware of this terrible disease, asked a Dr. G. E. Waring to deal with it in Havana, where it was rife. But Waring died of yellow fever, as had many millions before him, without knowing its cause, and it was left to Walter Reed, who died in 1902, to prove the connection between the mosquito and yellow fever. By a vigorous war on the mosquito, the disease has been eradicated from Havana and the West Indian islands, and Reed's discovery made possible the building of the Panama Canal (Ferdinand de Lesseps, the builder of the Suez Canal, had made a similar attempt in Panama, but had been beaten, amongst other factors, by yellow fever).

In yellow fever there is a sudden high temperature, aching of limbs and head, jaundice, and black vomit; the pulse-rate falls as the fever rises. Previous vaccination seems to be preventive if undertaken in time.

Conclusion.

All these virus diseases have this in common: that for many there is no specific cure, although smallpox, rabies, yellow fever, and poliomyelitis can be prevented by vaccination, or by the social control of the creatures carrying the virus. Some of the larger viruses (psittacosis, whooping cough) are destroyed by certain antibiotics. There is usually a long incubation period. Finally the question will sometimes arise of protecting some people from German measles or measles with gamma globulin containing another person's antibodies to the disease. This may be considered for measles in very young patients or to protect the foetus in pregnant mothers in contact with German measles.

Bacterial Diseases.

Bacterial diseases differ from virus infections in a number of respects: their incubation period tends to be shorter; having the disease once d not often confer lifelong protection; and un virus diseases, most bacterial diseases respon one of the antibiotics or sulphonanides. In m cases it is possible to inoculate against the dis to prevent it occurring, as we have seen is poss with only a few of the virus diseases.

Scarlet Fever and Other Streptococcal Infecti In the days, not so long ago, before the arriva chemotherapy (sulphonamides) and antibiot streptococci were very much feared and e caused a high mortality, particularly in s susceptible groups as children, and mothers babies in maternity hospitals. They are taken very seriously in the latter and rightly although one wonders how much of the mysti is simply a hang over from the days, thirty y ago, when many mothers died from "child fever." All signs of infection, such as fe during the puerperium (the period following ch birth) must be promptly dealt with by a doc and only occasionally now is there real cause anxiety provided treatment is prompt rigorous.

Scarlet fever is much less common and v much less serious an illness than it used to partly because of the effective treatments av able today, but also because of a definite but explained reduction in its severity. Perhaps streptococcus has changed, and certainly the proved physical condition of people who are much better fed and housed than they were, helped to ward off the terrors of this disease a so many other infections. The classical pict of signs and symptoms is now so rarely seen t it will not be further described.

The importance of streptococcal infections shifted from the initial infection, such as a throat, to some serious conditions which oc sionally arise as a result of some form of dela sensitivity to the bacteria. Acute rheumatism rheumatic fever (not to be confused with ordin aches and pains nor with rheumatoid arthr occasionally arise in people who have had a throat a few weeks before. Since the strep coccus is not the direct cause of the damage wh may consequently occur in the heart or kidn the antibiotics are no answer except someti to keep off further streptococcal invasions.

Diphtheria. This used to be an extrem serious disease, but immunisation has made almost unknown; it is important, therefore, t all children should be immunised. There many modern and up-to-date doctors who h qualified since the war who have never seen a c because it has become so rare, and in spite of propaganda of certain ill-informed people saving of children's lives is entirely the result nationwide inoculation during the war and si The following description is of historic inte only, and will remain so if a high level of inoc tion is kept up by parents.

In a typical case of diphtheria the incubat period is about three days; the patient is a c who becomes ill and pale-looking (*i.e.*, the o is not sudden, as in many fevers, but insidio the temperature is only slightly raised to, perh 99° or 101°, and although there may be no c plaint of sore throat, examination will reveal flammation with—and this is typical of diphth —a grey membrane spread over the tonsils, palate, and the back of the mouth genera The diphtheria germ does not spread within body. It stays at the place where it entered this case the throat) and sends its toxins throu out the body.

Even after the acute phase is over the pat must not be allowed to walk, because the diphth toxin is particularly poisonous to the heart. ordinary rule is at least one or two months in

Diphtheria also occurs in the larynx—in inoculation days many children choked to de with this form of the infection; in the nose; a although this is not generally known, wounds be infected. The so-called "Desert sores" the North African campaign seem to have b caused by diphtheria-like organisms.

Diphtheria may lead to paralysis of the thr with difficulty in speaking or swallowing, paralysis of the eyes or limbs; these are du

ritis caused by the influence of the toxin on nerves.

Whooping Cough. For many years whooping gh has been regarded merely as a bother to patient and a nuisance to others, as, in fact, a ial disease. Unfortunately, this is not so: ase statistics show that it causes more deaths n polio, diphtheria, scarlet fever, and measles put together.

Whooping cough begins in a child as an ordinary d with cough and slight fever, and this stage s for a week or ten days. Then the "par- smal stage" begins as a series of coughs owing in rapid succession, during which time patient is unable to breathe. The "whoop" caused by the noisy indrawing of breath when fit stops. The face may become blue and gested. Bronchitis is usually present, and nchopneumonia may result as a complication, inoculation of all children before the disease s a chance to strike them is most important. Once whooping cough has begun, there is no cific treatment, although modern drugs can luce the frequency of the fits of coughing. e antibiotic chloramphenicol has been used for s disease, but the general opinion is that it is inarily of little benefit. Chinese physicians ce described whooping cough as the "hundred- ys cough," and the cough may, indeed, continue at least a hundred days.

od Poisoning Diseases.

Strictly speaking, there is no such thing as ood poisoning" if one is thinking of "poison " in terms of anything apart from germs. t not so long ago it used to be thought that composition of food in itself produced poisons own as "ptomaines" which were deadly to ose who swallowed them. All food poisoning caused by infection of food with bacteria and no other cause—unless, of course, we are linking of the kind of poisoning which is the ncern of the lawyer rather than the medical an.

Here we are considering those diseases which are mmonly spread by contaminated food or drink. he classification is not scientific, but then no ientific classification has as yet been devised. irst, we shall deal with typhoid, paratyphoid, d dysentery—uncommon here in Britain, al- ough Sonné dysentery is fairly frequent. Then ere is gastro-enteritis (which means irritation the stomach and intestines), which is caused staphylococci and the germs of the salmonella oup, and lastly, botulism, which is rare.

Typhoid and Paratyphoid. These diseases are read by infected water, food, or hands—pecially uncooked food, such as milk, salads, sters, and shellfish. Flies, too, play some part spreading the disease. Some people are carriers" and carry and excrete the germs ithout being themselves affected; for example, Typhoid Mary," a carrier in the United States the early years of this century, spent a large art of her life in custody as a public danger, lthough she did not show any symptoms of yphoid. Nevertheless, this woman caused a reat deal of illness in others in her chosen rofession of cook.

The influence of Chadwick's propaganda for ure water supplies is shown by the fact that eaths from typhoid, still 332 per 1,000,000 in 870, fell to 198 per 1,000,000 at the beginning of his century. In the 1920s the death-rate was nly 25 per 1,000,000, and now it is even less.

Typhoid fever begins like most fevers with ea ache, raised temperature, and general feeling f unwellness. That stage lasts about a week, nd then the rash appears in the form of rose-red pots on the front of the chest and abdomen and on the back. In the second week there is great eakness, sometimes diarrhœa, flatulence, and ental dullness, together with dry and cracked ips and tongue. The third week is the week, in oneful cases, of gradual decrease in temperature nd other symptoms, and the fourth week is the eek of convalescence.

Complications are perforation of the intestine which needs surgical treatment), delirium, and bronchitis.

Paratyphoid fever is a milder form of typhoid (there are two forms, A and B); ordinarily it can be diagnosed only by scientific tests. The main thing is to inoculate contacts with T.A.B. vaccine and to protect food supplies; treatment is with chloramphenicol.

Dysentery. Dysentery may be caused *either* by a bacterium or an amœba; the first type is known as bacillary dysentery, the latter as amœbic dysentery (which is dealt with under tropical diseases). Infection is spread in much the same way as in typhoid. There is high fever, abdominal pain, and diarrhœa, at first consisting of fæcal matter, then blood and mucus. In severe cases the death-rate used to be over 20 per cent.

Various bacilli cause dysentery. The common tropical types are the Shiga and Flexner groups, but in this country most epidemics are due to the milder Sonné group.

However, in all these infections sulphaguanidine, one of the sulpha drugs, brings rapid relief, but care must be taken to avoid infection of other people.

Diarrhœa and Vomiting. Leaving out typhoid and paratyphoid fevers and dysentery, there is a group of infections known as "D. & V."—diarrhœa and vomiting. In Britain D. & V. is mostly due to:

(1) Salmonella infection.
(2) Staphylococcal infections.
(3) Other bacteria, ordinarily harmless, such as bacillus coli, when present in sufficient quantity.

Salmonella Infections are the most serious of this group; they affect the small intestine and produce vomiting, severe abdominal pain, and diarrhœa. These symptoms occur about one day after eating infected food and usually clear up within about two weeks, but occasionally death results. Salmonella bacteria are most likely to be found in meat, egg powder, vegetables, and ducks' eggs, but staphylococci are liable to grow in milk products, such as ice-cream and cream buns. Food poisoning from staphylococci is seldom severe, and recovery takes place in about a week. Nevertheless, it is extremely infectious, and causes a great deal of lost time in industry and temporary illness in institutions; for it is in such situations that it is most likely to occur.

Staphylococcal Food Poisoning has greatly increased in recent years, so it is important to know what circumstances are likely to cause it. The reason for its increase has nothing to do, as many people suppose, with the greater use of canned foods, but it has much to do with the greater use of communal feeding and canteen meals. It is *possible* for bacterial toxins in infected food to bring about illness even when the canning process has killed the bacteria, but it is certainly extremely rare. Canned foods, in fact, are much safer than so-called "fresh" foods in this respect—except when they have been opened, left about, and then re-heated. The same applies to the re-heating of any kind of food.

The real enemy is the canteen worker with a boil, a discharging nose, dirty hands, or a septic finger. Occasionally food may be infected in the larder by rats or mice, but the sort of canteen or restaurant where this can happen has little to commend it! Frankly, these infections are caused by dirty or stupid people who do not realise that their sore finger or boil can become someone else's diarrhœa and vomiting. Where children are concerned, the outlook is potentially more serious, and in the early part of this century the Summer-time "procession of baby coffins" was all too familiar. Infection is much more common in artificially fed babies or in older children who eat infected ice-cream. However trivial the condition may seem, diarrhœa and vomiting with fever in a child should never be ignored. Those in charge of canteens or restaurants must ensure that staff is supervised, that anyone with a septic infection is put off duty, and that all know about washing after visiting the lavatory and absolute cleanliness.

Bacilli normally present in the intestine, such

as bacillus coli, can cause infections if absorbed in large amounts, or if of a different strain from those in the patient's intestine. They are not usually serious.

Botulism. Now uncommon, this is the disease which used to be known as "ptomaine poisoning" on the theory that it was caused by poisons produced by bad food apart from germs. In the 1920s a party of picnickers at Loch Maree in the Scottish Highlands developed botulism and a number died, with the result that the disease attracted much public attention. Botulism is caused by a germ, the bacillus botulinus, which is peculiar in that, like tetanus, its poison attacks the nervous system rather than the intestines, resulting in tits, double vision, paralysis beginning in the face and spreading downwards, and difficulty in swallowing. It is found in tinned fruits or vegetables containing the toxin even when the germ has been killed, but, as we have already seen, the toxin comes from the bacilli, not from decomposition of food as such (in fact, food does not decompose in the absence of germs). Death is common in botulism, but an antitoxin is now available, which, if used in time, can cure the disease.

Tuberculosis. No disease causes more public concern, and no disease is more difficult to describe, than tuberculosis; for, like the streptococcus or the staphylococcus, the tubercle germ can attack many different parts of the body and manifest itself in many ways. Furthermore, it is a widely spread disease, infecting not only humans but also cattle, birds, and reptiles. But here we shall be concerned with those types common to Man—the human and bovine (*i.e.*, the type occurring in cattle which can be spread to man by infected milk).

The tubercle bacillus is particularly hardy, so that when coughed or spat out on the ground it continues to be infectious for a long time. Infection is therefore caused by: (*a*) drinking infected milk; (*b*) droplet infection through having germs coughed in the face; (*c*) breathing in infected dust. In other words, tuberculosis is caused by absorption through either the lungs or the intestines; the former is common in adults, the latter in children.

But there is a good deal more to the problem than this; we know, for example, that over 90 per cent. of people in industrialised countries have been infected with T.B. in early life and have conquered the infection. So the question arises: what conditions predispose to T.B.—why do some people get over the early infection and others not? There are two answers to this question: one is certain—that those who are impoverished and do not get enough food are liable to T.B.; the second is not so certain—that mental stress plays some part. Yet there is reasonably good evidence that such stress as a broken love-affair can cause lowered resistance to breakdown so that when germs are encountered infection will occur.

In children, lung tuberculosis is not common, but tuberculosis of the bones and glands is, as is also infection in the abdomen, the kidney or spine, and, worst of all, tuberculous meningitis. These are often of the bovine type from infected milk. Ordinarily, T.B. in children is less serious than adult infections; but tuberculous meningitis used to be almost invariably fatal until streptomycin was discovered.

Adult tuberculosis usually occurs in the lungs or the pleura—the thin membrane surrounding the lungs. In younger people miliary tuberculosis, which is a form of T.B. blood-poisoning or septicæmia, is a very serious condition, and the infection spreads throughout the whole body in a few weeks.

Lung infection begins gradually in someone who has previously felt unwell. There may be cough, and later blood-stained sputum (although blood which is coughed up does not necessarily prove that T.B. is present). Whatever means of treatment are used, the struggle between disease and patient is likely to be fairly long, but the outlook is now good. The closure of the Swiss sanatoria is due partly to modern disbelief that air in one place is better than that in another, but mainly to improved treatment.

Prevention depends on legal action ensuring tuberculosis-free herds of cattle; on control of spread of the disease by those "open" cases who carry germs in their sputum; on the use of vaccination in childhood with B.C.G. vaccine (which you can ask your doctor about).

Many methods are used in treatment: new drugs, such as streptomycin, isoniazid, and P.A.S., lung surgery, rest, and so on. At any rate, tuberculosis is being got under control, but anyone who is worried can get a free X-ray at the nearest Mass Radiography Centre. For children, there are skin tests to show whether there is susceptibility to T.B.

Septicæmia. Commonly known as "blood-poisoning," is one of those diseases of which textbooks prior to the Second World war used to say: "death usually occurs."

Blood-poisoning occurs generally by spread from some septic area such as a wound (or even a small prick), after childbirth, or any place where certain germs have got admission to the body. The most usual germ is the streptococcus, although the pneumococcus—which ordinarily causes pneumonia—and the staphylococcus may also cause septicæmia.

Fever comes on suddenly and rises rapidly with headaches, sweating, and shivering. The patient is obviously very ill, and later there is wasting and delirium. The white blood cells increase in number. Septicæmia sometimes occurs without any apparent local infection in those who are weak and debilitated.

Pyaemia is a type of septicæmia which leads to the formation of numerous abscesses throughout the body. Its symptoms are the same as described above, except that the causative germ is usually the staphylococcus, and abscesses are found which may need surgical treatment.

However, in both conditions the state of affairs has been revolutionised by the use of the sulpha drugs and antibiotics; cure is now the rule rather than the exception.

Septicæmia should be suspected when any small wound or cut is followed by high temperature and the symptoms described above.

The word "*Toxaemia*" is used when the germs stay in their original position and produce symptoms by spreading their toxins throughout the body. Tetanus, diphtheria, and some kinds of childbirth infection come into this category; the symptoms may vary from mild disturbance to severe illness.

Meningitis means inflammation of the meninges, the covering which, like a layer of plastic, lies over the brain and spinal cord, just as the pleura covers the lungs and the peritoneum covers internal organs in the abdomen. (Hence inflammation of the pleura is known as pleurisy, and inflammation of the peritoneum as peritonitis.)

Various germs may cause meningitis, for example, the bacillus of tuberculosis, the pneumococcus, which ordinarily causes pneumonia, and the streptococcus or staphylococcus, but ordinarily the word refers to *Cerebrospinal Meningitis* or "spotted fever" caused by the meningococcus and occurring at times as an epidemic. It is commonest in the years from infancy to the early twenties, and begins suddenly with headache, vomiting, and fever. The temperature rises quickly, and pain develops in the back and legs; on the second or third day a rash appears on the body, and particularly on the inside of the thighs. Later there is stiffness of the neck, the head may be drawn back, vomiting persists, and the headache can be so severe as to cause the patient to scream with pain.

Fortunately, this type of meningitis (and most of the others) respond to treatment with antibiotics or the sulpha drugs, so the risks are very much less than formerly.

Pneumococcal Meningitis is an unusual complication of pneumonia, and the septic types (*streptococcal or staphylococcal*) arise either following an infected fracture of the skull or from infection of the ear or mastoid.

Tuberculous Meningitis has already been mentioned; originally always fatal, it is now treatable with streptomycin.

All these diseases are very much a matter for

specialist and hospital treatment, but it is worth while mentioning *benign lymphocytic meningitis*, in which, although all the symptoms of meningitis are present, recovery without specific treatment is invariable. Meningitis, which was during the First World War and after what polio is to us now, is no longer common, and when taken in time is easily treated.

Tetanus is usually known as "lockjaw" because there may be difficulty in opening the mouth, although this is simply part of a spasm of all the muscles of the body. The tetanus bacillus is found in rich soil—hence the disease is less common in desert areas—and tetanus resembles rabies in that: (*a*) it enters at a wound; (*b*) it affects the nervous system; (*c*) it results in fits and ultimately death.

However, active immunisation with T.T. (tetanus toxoid) has resulted in the disease becoming uncommon, and even when developed, treatment with antitoxin, anæsthetics, and curare may lead to cure.

The bacillus is anærobic (*i.e.*, does not use oxygen) and is most likely to occur in such situations as when a man digging manure or working in his garden sticks a fork through his foot, or, in war-time, when he is wounded in soil contaminated with manure.

Undulant fever, also known as Malta fever or abortus fever, falls into two types: melitensis, which infects goats, and abortus, cattle and pigs. Man gets the disease by reason of close contact with or drinking the milk of infected animals. (The name abortus is given because abortion is produced in cattle and sows.)

In Undulant Fever, as one would suppose, the fever goes up and down for two to three weeks, it may then go down and rise again, persisting for many months. The disease may occur in Britain, but modern drugs are on the whole successful in dealing with it. A striking feature of the disease is the combination of a high temperature with an appearance of relative well-being.

Another disease carried by mammals is *Glanders* or *Farcy*, spread by horses. In glanders there is discharge from the nose and sometimes pneumonia. Occasionally the disease is fatal. In farcy abscesses form, usually along the lymph vessels. Both conditions are very contagious, and treatment is a matter for a specialist; infected horses should be destroyed.

Cholera. Cholera could be classified under the head of food-poisoning, because it is mainly spread by infected water (however, like typhoid, it can also be spread by flies, infected food, and carriers); it could also be classified as a tropical disease, since, although it used to be found in Europe, it is now mainly rife in India.

Also like typhoid, cholera is caused by a bacillus, and can be prevented by early innoculation and care over food supplies—boiling water and milk, washing uncooked foods in chlorinated water, and keeping flies away.

The fever begins in the usual way with a short incubation period, followed by abdominal pain, severe vomiting, and diarrhœa. Later with the loss of fluid from the body there may be cramps in the muscles, diarrhœa increases, and the motions become of the typical "rice-water" type —*i.e.*, there is no solid matter, and the appearance is that of water to which a little milk has been added. This stage is followed by collapse, with low pulse and cold hands and feet. Death, if adequate treatment is not available, results in about 70 per cent. of cases.

Anthrax. The bacillus of anthrax, like that of tuberculosis, can exist outside the body for long periods, and, like that of tetanus, then takes the form of spores or seed-like bodies. It is spread by infected cattle and horses, which get the disease from eating grass containing spores.

In human beings the form the disease takes depends on where the germ alights; sometimes it comes from infected shaving-brushes, when it causes a large sore, like a boil, on the face, known as "malignant pustule"; sometimes it develops in those who inhale the dust from infected hides or wool (hence the name "wool-sorters' disease," which is a form of bronchitis with blood-stained sputum); lastly, it may arise through eating infected meat, when the result is intestinal anthrax.

In all cases the outlook is serious. Death is common, preceded by a high temperature, skin symptoms in the first instance, lung symptoms in the second, and food-poisoning symptoms in the third. Serum and arsenical preparations were formerly used, but now the sulpha drugs seem to offer more promise.

Diseases Caused by Fungi.

There are only two important groups of disease caused by fungus: the serious *actinomycosis* and the relatively harmless, if unpleasant, *ringworm*. Ringworm or tinea will be dealt with later; it affects the hair, the body, the groin (dhobie itch, already referred to), and the feet (athlete's foot). Actinomycosis is spread by a fungus in barley and grasses which may reach the human mouth, settle around bad teeth, and thence pass to the lungs, the bone of the jaw, and even to the intestines or brain. Fortunately, this unpleasant fungus, which was once difficult to eradicate, has proved susceptible to penicillin.

The Venereal Diseases.

The venereal diseases are those caused—or at least that is what the name means—by the goddess of love, Venus. Venus, of course, causes a great deal of trouble, but venereal disease is not necessarily the worst she can do. There are two diseases usually caused by sexual intercourse, and therefore described as venereal; others can be caused in this way, but are not usually so described.

Gonorrhœa is the result of an infection by the gonococcus (*Neisseria gonorrhœa*) and ordinarily comes on after a period of three to seven days following intercourse. However, babies can get an infection of the eyes, known as ophthalmia, from their mother if she is infected, and gonorrhœa in young children is often the result of being in contact with infected towels or clothes. The disease in adults is evident when there is a thick, creamy discharge from the sexual organs and sometimes pain on passing water; in infants ophthalmia is prevented by the use of silver nitrate eye-drops at birth. Gonorrhœa is fairly easily cured by the use of sulpha drugs or penicillin; but unfortunately venereal disease is increasing in recent years and drug-resistant forms are becoming more common.

Syphilis is more serious, and is nearly always caused by sexual intercourse. Stories about lavatory seats are simply stories, although it is occasionally possible to get syphilis by other than sexual means: for example, it has happened that a man playing football has been infected through his hand being grazed by the teeth of someone with syphilis. But this is very unusual, although kissing can spread the disease. Children, too, can be born with syphilis (the so-called congenital syphilis).

Adult syphilis begins with a sore, known as a hard chancre, at the point where the spirochæte of syphilis has entered; this may be on the lips, through kissing; on the sexual organs, through intercourse; and very rarely, as explained above, elsewhere. In a short time the chancre disappears and all may seem to be well, but this primary stage is followed by a secondary stage with sore throat, a rash, headache, and enlargement of glands. This, if left alone, also clears up, but is followed by the tertiary stage, in which a chronic infection develops in some part of the body which, presumably, is most susceptible in the particular individual. Thus there may be chronic syphilis of the skin, the bones, the heart, liver, or nervous system.

In the nervous system, the commonest forms are the two diseases of *tabes dorsalis*, in which the spinal cord is infected, and G.P.I. (general paralysis of the insane), in which the brain and mind are affected. These will be discussed under Nervous Diseases.

In congenital syphilis the pregnant mother gives her child syphilis. Such infants are often stillborn or premature, they look wizened, like a little old man, and amongst other symptoms are eye

disease, "snuffles," a flattened nose, and when the adult teeth appear the front ones may be notched at the biting surface.

The treatment, of course, is very much a matter for a specialist, but diagnosis is usually made through the Wassermann blood test. It was for syphilis that Ehrlich produced his "magic bullet"—an arsenical drug, known as salvarsan, which could attack the organism selectively without harming the body and was the first of the modern specific drugs. Present-day treatment is with penicillin. G.P.I., once hopeless, is now dealt with by malarial therapy with a good deal of success. Penicillin alone is often adequate.

It is important to understand about venereal disease in general: (1) that it happens to many people who are no worse than anyone else; (2) that many patients believe themselves to have V.D. when, in fact, they have not; (3) that the best thing to do is to see your doctor as soon as possible—he is not concerned with your morals, and the sooner you go, the sooner you will get well; (4) every sore in the sexual area need not be V.D. There are other diseases which may be contracted as venereal infections.

Chancroid produces small septic ulcers around the sex organs, with swelling of the local glands in the groin, which may suppurate. It is caused by a bacillus, and can usually be cleared up by sulpha drugs within a week. Scabies and lice often pass from one body to another during sexual intercourse, but are not usually thought of as venereal in origin, although in many cases they are.

Tropical Diseases.

Nothing is more difficult than to define the term "tropical diseases." One might define them as the diseases which occur in tropical climates—but then measles occurs there too; and if they are defined as those diseases which are found *only* in the tropics, the solution is no easier, since leprosy, cholera, smallpox, and typhus are usually listed as tropical diseases, yet were found in this country until fairly recently—and the odd case still is.

But what a story could be told about the conquest of those infections which were—and many still are—the scourge of humanity! One day when generals and dictators are forgotten we shall remember that great international army of physicians and bacteriologists who have saved millions of lives and infinitely reduced human suffering: Koch and Ehrlich of Germany, Pasteur and Roux of France, Ross and Jenner of Britain, Reed of America, Noguchi of Japan, and many others. We shall remember how the Jesuit priests brought quinine from Peru to Europe in 1638, the first drug to save people from malaria; how in tropical heat Ronald Ross (1857–1932) peered for hours through his microscope to discover the connection between malaria and the mosquito until the sweat running from his brow rusted the instrument; how Major Walter Reed's work in Havana (1851–1902) made possible the building of the Panama Canal, and think, too, of the American soldiers who died in helping him to find the cause of yellow fever. In mentioning Jenner once more, we should recall Lady Mary Montagu (1689–1762), who brought the practice of vaccination to England from Turkey—or, rather, the practice of "variolation," which meant inoculating with the pus from smallpox cases. This was, of course, a dangerous practice, but the idea was there. Noguchi, one of the great bacteriologists of the nineteenth century, was the son of a poor peasant. He often had to steal to get enough bread even to keep alive, but was later to help in our understanding of syphilis and many tropical diseases.

Yet there is still much to do. Take, for example, the case of Egypt, one of the world's poorest countries, supporting with the help of water from the Nile about 24 million people. But if the river gives food and drink it does other things; for it carries the disease of bilharzia, which kills thousands of peasants yearly. In the villages of Egypt as many as 90–100 per cent. of the population suffer from this terrible disease. The infantile mortality rate is the second highest in the world—29·5 per cent.—seven times higher than that of Holland; the average expectation of life amongst the lower classes is thirty-one years, of the upper classes fifty to sixty years. The country is ridden with bilharzia, ankylostomiasis, malaria, plague, amœbic dysentry, typhus, tuberculosis, and pellagra. Blindness, due to trachoma and other diseases, affects tens of thousands. Such a situation cannot be treated simply by pouring drugs into the country; what is necessary is social control, to enforce purification of the water supplies, the use of insecticides such as D.D.T. to kill the disease-bearing pests, and removal of the causes of extreme poverty (tuberculosis and vitamin deficiencies which are common in Egypt are diseases of malnutrition).

Relapsing Fever, common in India and Africa, is caused by bad hygiene (rubbing infected lice into the skin); the germ is a spirochæte, similar to that of syphilis, but the disease is non-venereal. Relapsing fever gets its name from the fact that the temperature remains high (103–106°) for about a week, returns to normal for a week, and rises again. There may be three to five relapses of this sort. Cure can be brought about by the arseno-benzol drugs used in syphilis. Lice, of course, should be dealt with.

Epidemic Jaundice (also known as Weil's disease or—if you prefer it—ictero-hæmorrhagica spirochætosis), is also caused by a spirochæte, and spread by rats. Now it is rarely found in Europe, although it occurred in the trenches during the First World War, in men working in sewers, and in the women who worked in the fish market of Aberdeen, which at one time was rat-infested. It is rarely fatal, but leads to high fever and jaundice. Anti-syphilitic drugs are useless, but some of the new antibiotics may help.

Yaws is also a spirochætal disease, common in the tropics and particularly in children. It is unpleasant, but not serious, and tends to clear up in a year or so. There are raspberry-like growths on the skin, which disappear with the drugs used in syphilis (although the condition is non-venereal). The Wassermann reaction, positive in syphilis, is also positive in yaws.

Leprosy. Whereas syphilis, relapsing fever, epidemic jaundice, and yaws are caused by spirochætes, leprosy is caused by a bacillus resembling the bacillus of tuberculosis. Leprosy, in fact, should not be included here at all, for it is non-spirochætal, and not necessarily a tropical infection. Apart from the difficulty of classification, many popular beliefs about the disease are untrue. It is *not* the oldest disease afflicting man; *not* a disease confined to tropical countries; it is *not* very catching; *not* hereditary, *not* incurable; in leprosy the fingers and toes do *not* drop off; it is *not* a divine punishment for wrongdoing. So there are many misunderstandings about this disease, and placing it in the wrong part of the medical section is probably the least.

Leprosy is a serious disease not because of disfiguring light-coloured skin patches and lumps, but because it destroys peripheral nerves. Leprosy may disappear spontaneously, or it may progress until the face is lion-like and the hands and feet wasted and ulcerated. The disease rarely kills, but it is the world's greatest crippler.

Leprosy was once fairly common in colder Western countries, though its extent was exaggerated. The great majority of the 15 million people who suffer from leprosy live in tropical countries, but it still exists in Iceland, Japan, Korea and some of the southern states of the United States. Prolonged and intimate contact with an "open" case is said to be the main mode of infection, but only one infected husband in twenty passes leprosy to his wife.

The sulphone drugs have revolutionised the treatment of leprosy. Given early diagnosis and adequate treatment, the great majority of sufferers could be cured. Established deformity (such as claw hand, drop foot, paralysed eyelids) can be mitigated by reconstructive surgery, although lost sensation cannot be restored.

In the past, only Christian missions were concerned with the plight of the leprosy sufferer. Now, non-sectarian voluntary agencies, Governments and the World Health Organisation have joined in the fight against the disease. Enough is known to control the disease, but not enough is

being done, as only one victim in five is at present getting treatment.

Plague is another disease caused by bacteria, common in Europe at one time, but now largely restricted to Asia. Nevertheless, it caused millions of deaths in Europe during the years 1348–49 and 1665 and was the "Black Death," which, indeed, changed the course of history. Interested readers may read Hans Zinnser's *Rats, Lice, and History* about this aspect of the disease. Plague is carried by the bite of the rat flea, but, once people become infected, spread may occur from one to the other by droplet infection—*i.e.*, by coughing and sneezing. After an incubation period of two to ten days, fever develops, rather like severe influenza, and in a day or two the glands in the groin begin to swell, followed perhaps by swelling of the glands elsewhere. This is the usual type of plague, but it is also possible to get disease of the lungs from droplet infection and blood-poisoning from infection of the blood-stream. Both the latter types are almost invariably fatal, and even the glandular type (bubonic plague) has a mortality of about 80 per cent. The vaccine has given place to streptomycin and sulpha drugs which are also used on contacts.

Although we have little space to discuss the subject of plagues and epidemics in general, it is worth noting that serious epidemics have almost always followed wars, revolutions, and economic and political collapse. Thus the Black Death followed the break-up of the Roman Empire, and, in the fourteenth century, accompanied the end of mediæval civilisation. The Napoleonic wars were followed by other epidemics, and the wars of the 1830s in Europe were followed by influenza. In the most widespread outburst of influenza after the First World War, more people were killed by the disease than in all the fighting of four years. It is a reflection on the peculiar mentality of Man that this devastating epidemic, which affected almost the whole world, occupies little space in his history books—we still, with few exceptions, regard history as the doings of kings, queens, and generals. Yet, in 1918, 20 million men, and women, and children died from influenza, and no cure has, as yet, been found. Later we shall see that many millions of people die yearly from starvation or vitamin deficiencies But these facts—the real facts of life—we rarely hear about.

Protozoal Diseases.

Nearly all the diseases caused by protozoa are tropical diseases, although one of the best-known protozoans is the harmless amœba found in British ponds. Protozoal diseases are caused by these organisms, large in comparison with bacteria which are really one-celled plants. Viruses are neither animals nor plants, are much smaller than the other two groups, and have some distinctive characteristics described elsewhere.

The only important diseases caused by protozoa are sleeping sickness or tryanosomiasis, malaria, and amœbic dysentery (as contrasted with bacillary dysentery), another disease, leishmaniasis—also known by the numerous names of kala-azar, dum-dum fever, and, in milder form, Delhi boil, Oriental sore, or Bagdad sore—will also be mentioned briefly. These infections are few, but important in their influence on Man; for, as Dr. Clark-Kennedy has pointed out, malaria until recently was responsible for one-fifth of the human sickness, sleeping sickness not so long ago caused a large part of Central Africa to be uninhabitable, and in some areas of the tropics there are probably more people with, than without, amœbic dysentery.

Malaria. The word, of course, means "bad air," just as "influenza" means "influence"—in Italian *influenza di freddo*—the influence of cold. Human beings have a natural tendency to suppose that, when two events occur together, then one must be caused by the other. Yet, although malaria and "bad air" may often go together, and influenza and cold, it does not follow that bad air (whatever that may be) causes malaria nor that cold causes influenza. In fact, the anopheles mosquito carries the amœba of malaria, and the mosquito prefers climates which some people might describe as "bad," but it is the amœba, not the air, which causes the disease. Anyhow, the unfortunate mosquito might well use the phrase honoured by many generations of schoolmasters: "It hurts me more than it hurts you!" For the mosquito, too, is sick, and passes on its sickness to the person it bites.

There are several types of plasmodium—which is the scientific name for this amœba—producing attacks of fever varying in severity and frequency: benign tertian, quartan, and malignant quartan. Entering the body from the mosquito bite, the parasites penetrate the blood cells, multiply there, and finally burst into the blood stream. When this happens the temperature rises, and then they return to the cells to carry out once more the same procedure. Depending on the type, the attacks of fever may be at intervals of three or four days, severe or milder. When someone with malaria is bitten by a mosquito the infection can be transmitted to the next person it meets, but malaria is not infectious from one person to another directly. Quinine, of course, is the time-honoured remedy, but many other drugs are now available: mepacrine, palmaquine, atebrin, and even a sulphonamide derivative known as promin have been tried. The drug must be taken long enough for the infection to die out, otherwise relapses can occur even after leaving a malarial country (but it is only fair to say that, just as some people continue to give themselves the title of "Major" when they have left the Army, so the sahibs long in Britain continue to describe attacks of cold or 'flu as "my old malaria again," when, to say the least of it, they are exaggerating).

Important as are the drugs used in the treatment of malaria, even more so is the control of the parasite-bearing mosquito. The eggs of mosquitoes hatch in water, and there the young or larval forms can be attacked by pouring oil on the surface of pools so that they are unable to breathe, or by introducing small fish which have a partiality for them. Adult mosquitoes can be killed by D.D.T. and other insecticides or kept away by nets over beds and skin creams. Finally, anti-malarial drugs can be taken in dangerous areas. Whereas anopheline mosquitoes were once well on the way to getting rid of Man, now Man is well on the way to getting rid of mosquitoes.

Blackwater Fever is a sequel to malaria in tropical Africa and some parts of India. Rather illogically, it is described as "Blackwater," although the urine is red and the skin is yellow but the result is due to breaking down of the red blood cells by some malarial toxin. Possibly too much quinine may help in producing the illness. Treatment is to give plenty of fluids and no quinine or any other anti-malarial drugs in the early stages. The death-rate is about 25 per cent.

Trypanosomiasis or sleeping sickness—not to be confused with *sleepy* sickness, which has already been dealt with under the name of encephalitis lethargica—is essentially an African disease (although also found in tropical America) spread by the tsetse fly. Its cause is the type of protozoan known as a trypanosome, almond-shaped with vibrating membranes at the sides which enable it to move through the blood-stream, rather like a flat fish in the water.

There are three stages of the disease: first, the stage of fever with enlarged glands and a rapid pulse, which may continue off and on for three years; secondly, the stage of trembling hands, legs, and tongue, vacant expression, and slow and stumbling speech; thirdly, and lastly, the stage of low temperature, apathy, wasting of the muscles, and possibly death.

Treatment is with arsenical drugs—such as tryparsamide or Bayer 205—which give good results in early cases. Preventive measures in infected areas include the destruction of tsetse flies by insecticide, the cutting down of forests near rivers which are inhabited by tsetse flies, and some authorities have suggested the shooting of big game which may form a "reservoir" of the parasites, whence tsetse flies can carry them to human beings. For similar reasons infected

people should not be allowed to move to non-infected areas.

Amœbic Dysentery, also known as *Amœbiasis*, is caused by the *Entamœba histolytica*, an amœba whose cysts are found in food, water, or spread by infected fingers or flies. There is mild fever and diarrhœa which contains blood. The disease may become chronic, and can cause abscesses, usually in the liver but sometimes in the lungs. Amœbiasis is treated and usually cured by injections of emetine hydrochloride, but in the chronic phase the drug known as Yatren is used in the form of an enema.

Leishmaniasis, kala-azar, or dum-dum fever, is another amœbic disease, probably spread in this instance by the bite of sandflies. It is also known as tropical splenomegaly—enlargement of the spleen in ordinary language—since infection results in enlargement of the spleen and liver, low, irregular fever, and death within a year or so. A milder form, affecting the skin, is known as Delhi boil, Oriental sore, or Bagdad sore, does not lead to kala-azar, and is fairly readily cured. The cure for both conditions is to give injections of tartar emetic, which reduces the death-rate from kala-azar from 80 per cent. to about 5 per cent.

Diseases Caused by Parasitic Worms.

Many types of worms infest human beings and other animals. They are interesting for such reasons as their size (which may range from the almost invisible to 30 ft. or more), their life histories, and their serious or trivial consequences on their hosts. We shall mention only a few groups here, and mainly the ones likely to be met with in Europe—the tapeworms, the roundworms, and the threadworms—although some tropical types will be described briefly.

Tapeworms, as we have seen earlier, like many other types of intestinal worm, lead a double life. What usually happens is that the worm breeds in the human intestine, the eggs pass out in the fæces, and are then swallowed by animals eating contaminated material. In the animal the eggs hatch out into larvæ—primitive forms which penetrate the muscle, forming cysts—and Man is infected in turn by eating its meat. Thus *taenia solium* gets into the flesh of pigs, which, if imperfectly cooked (measly pork), causes infestation of the intestine in Man. It reaches a length of about 10 ft. *taenia saginata*, which reaches a length of about 20 ft., is spread in imperfectly cooked beef, and in Baltic countries *dibothriocephalus latus* gets into the human intestine from caviare or undercooked fish. It reaches the awesome length of 30 ft.

Now all the worms we have mentioned so far are found in the human intestine, and the cysts, which are much more dangerous and unpleasant, in the animal's muscles. But in some worms the reverse happens, with the adult in the animal's intestines and the cysts in Man. Thus in Australia the dog tapeworm (*taenia echinococcus*) produces cysts in both sheep and Man. This is known as hydatid disease, and may remain unsuspected until cysts in the lungs, liver, or elsewhere become infected or rupture. *Trichinella spiralis* is similar in action, being found in the intestines of pigs and getting into the muscles or other organs of Man. The main difference is that this worm migrates from the pig's intestines into its muscles, whence it reaches Man in undercooked pork meat or sausages. The muscular cysts cause swellings and sometimes pain. There are changes in the blood, swelling of the face and leg in the early stages, and fever. A minor epidemic occurred in England in 1941. *Taenia echinococcus* and *trichinella spiralis* are small—not more than ½ in. in length—but are more serious in their consequences than the large worms. Treatment is very difficult, and ordinarily all that can be done is to deal with individual cysts when they make themselves apparent.

The large tapeworms, *taenia solium* and *saginata* and *dibothriocephalus latus*, produce varying symptoms or none at all. Usually they are not discovered until some segments of the worm are excreted, but there may be mild indigestion excessive hunger, and occasionally anæmia. However, when the worm is discovered the patient not unnaturally, is likely to become anxious and uncomfortable at the thought of "having" a tapeworm; these symptoms are caused by the worry rather than the worm.

Treatment is, of course, a matter for a doctor but purging followed by extract of male fern is usually successful. One has to make sure that the head of the worm has been removed, otherwise it will continue to grow.

Roundworms are similar both in appearance and size to ordinary earth-worms and the eggs reach Man, not from an animal, but from the contaminated fingers of someone else who handles food. They give rise to no symptoms, and are noticed only when discharged in the fæces or occasionally vomited up. They can be removed by the use of santonin.

Threadworms, as the name suggests, are like small ¼–½-inch-long pieces of white thread. They are very common in children, and live mainly in the cæcum—*i.e.*, the part of the large intestine near the appendix. The males, which are the smaller ones, remain there, but the females pass down towards the rectum at night-time and lay their eggs in the area around the anus. Infection is by contaminated hands handling food—especially uncooked food—and water. Threadworms are not serious, and cause few symptoms other than itching around the anus and between the legs, but heavily infected children may show symptoms of anæmia. The nervousness often shown by such children is usually the result of the irritation produced by the worms in the anal region. Infection is not common in adults, and in children tends to disappear at puberty.

Treatment is, in theory, simple; for the worms are easily destroyed by a number of drugs, such as gentian violet, thymol, or one of the proprietary remedies. Ointment is applied to the itching area, and the child should be prevented from scratching. However, since the eggs may live about the house for some time, reinfection often happens, especially if there are several small children in the home who may pass the disease from one to another.

The idea that intestinal worms in general are likely to cause loss of weight by absorbing food eaten by the patient is largely mistaken: for although it is true that they do live on this food the amount taken is certainly not enough to be significant.

Tropical Worms. Bilharzia has been mentioned before in connection with its frequency in Egypt, although it is also found in other parts of Africa, Arabia, and Iraq. There are two main types: one infecting the bladder (*schistosomum haematobium*), the other the rectum (*schistosomum mansoni*). Bilharzia is more correctly known as schistosomiasis.

The parasite's fantastic life-history begins when a man bathes in infected water, and the small swimming forms known as cercariæ pierce and enter his skin—or they may enter the body by drinking infected water. From the skin they pass to the portal vein below the liver, remain there six weeks until they become adult and then swim against the blood-stream down to the pelvis, where the female lays eggs which have a sharp spine. The eggs penetrate into the bladder or rectum—depending on the type of fluke—and pass out in the fæces or urine. If they enter water they hatch out into small moving forms which seek out a water-snail, develop further in its body, and leave it in the form of cercariæ ready to find a new human victim. The female fluke is slender and round, about 1 in. in length, the male, flat and leaf-shaped, is about ⅔ in. long, and as we have seen, their grisly courting takes place in the portal vein, whence the impregnated female

passes to the bladder (hæmatobium) or rectum (mansoni) to lay her eggs.

Infection results in raised temperature and, in the urinary type, blood in the urine; in the intestinal type blood is found in the fæces, and there are symptoms resembling dysentery—*e.g.*, diarrhœa. Treatment in both cases is by injections of antimony tartrate. Needless to say, attempts should be made at prevention by telling people to avoid infected canals (usually easier said than done), and by periodically cutting off the water supply to the canals to kill the snails.

Hookworm Disease, or ankylostomiasis, is found in many parts of the world, especially in miners who work on damp ground. The tiny worm enters the body usually through the feet, passes through the blood-stream to the lungs, eats through into one of the bronchial tubes, climbs the windpipe, and passes down the œsophagus into the stomach to end up in the duodenum. It causes anæmia, can be fairly readily cured, but is occasionally fatal.

Elephantiasis. Some types of parasitic worm are spread by insects. Thus in *Filiarisis* mosquitoes inject by their bites the infantile forms of a tiny worm which enters the lymphatic channels; there the blockade they cause leads to the swelling of the legs and the lower part of the body, known as elephantiasis.

PHYSICAL INJURIES

INTRODUCTION.

In this section we shall inevitably discuss much that could be described as Principles of First Aid. You cannot learn First Aid from a book, even if you read one of the excellent first aid manuals, like those published by the St. John Ambulance Association. The only way is to join one of their many classes of practical and theoretical instruction which are held in all parts of this country and many others. There is much to be said for many more people receiving instruction, to judge by the level of general ignorance and ineffectiveness to be witnessed at most road accidents before the ambulance comes.

The most difficult thing to learn is what *not* to do. When a patient is knocked down in the road, people instinctively seem to want to drag him immediately to his feet, or otherwise pull him on to the pavement away from the traffic. Someone will have entered the nearest shop and be emerging with a chair so that the casualty can sit down. Before long a hot strong sweet cup of tea has arrived, and this or some other beverage is being poured into him. All this is instinctive, and all of it is wrong. Do *not* move the patient until you are sure he has no fracture which will be further aggravated by movement. To take an extreme case, a fractured spine clumsily moved may result in permanent widespread paralysis. Guard your patient from the traffic but only move him when you are certain it is safe to do so. If he has any injury which is likely to require a general anæsthetic on arrival in hospital (and this applies to most fractures) do not give anything at all by mouth. No anæsthetic can be given to a patient who has eaten or drunk anything in the previous three hours, in case he vomits while unconscious and dies of obstruction of his airway. Keep your patient warm (do *not* warm him up artificially) keep his head low, and unless he is bleeding severely or has stopped breathing, do nothing but protect him from the ministrations of the uninstructed until the ambulance comes.

Injuries to the Head and Back.

The head contains the brain, an organ with a number of inconvenient properties from the point of view of injury. Its very great importance is matched by its very great vulnerability as a tissue. Its consistency is that of stiff junket. It is quite incapable of repair once damaged and cannot heal by growing new parts in the way that skin and bone can. So it has to be totally enclosed by protective bone which means it cannot swell without compressing itself dangerously within its box—and this not infrequently happens after injury. Furthermore, any bleeding into the interior of the skull can only occur at the expense of compressing the brain, since the brain box is already fully occupied by the brain. There is a story in first aid known as "Concussion and Compression." It begins with a knock-out blow to the head and this is known as concussion. The patient struck a hard enough blow to the head will lose consciousness, if only for a short time, due to the brain being shaken up. Even slight knocks would do this if the brain were not cushioned by a thin layer of cerebrospinal fluid. Most concussed patients quickly regain consciousness, and for the great majority that is the end of the affair except for a sore head and a headache for a few days. Unfortunately for a minority, even though there may have been no fracture, the blow that knocked them out will also have damaged a small blood vessel on the surface of the brain. These patients may be indistinguishable from the luckier ones at first. They may have regained consciousness and will be just as anxious to go home. They will often be quite lucid for some hours. Surgeons call this the "lucid interval." However, when more than a certain amount of blood has accumulated in the head, and the brain is sufficiently compressed by it the patient loses consciousness slowly, for a second time, and from this phase of "compression" he will not recover unless something is done. The lucid interval can last some hours. Brain surgeons can relieve the compression and save the life of the patient only if they have him in their care when it occurs. This is why *all* cases of head injury who have once lost consciousness (concussion), for however short a period of time, and however lucid they may subsequently appear, *all* must be seen by a doctor and, if thought necessary, observed overnight in hospital, in case they are bleeding and proceeding to compression. There is no way of saving these avoidable fatalities other than by treating all cases of concussion seriously. Fractured skull is potentially even more serious, because the blow will have been harder and, the brain is therefore more seriously at risk.

The spinal cord can be regarded as an extension of the brain which runs down the middle of the spinal bones of the vertebral column. It has the same delicate consistency, and the same inability to recover from injury as the brain. Injury is usually the result of a fracture-dislocation of the spine. The consequences of injury are due to a permanent interruption of its two main functions. All movements of the voluntary muscles are only possible if they are connected by nerves to the brain. Except for muscles in the head, all these "motor" nerves run in the spinal cord. The nerve pathways leave the skull through a large hole in its base and run down in the spinal cord to the required level. They then emerge between the spinal bones and travel in bundles to reach the muscles. Motor nerves for the arm leave the cord between the vertebrae of the neck. Those for the leg leave the cord in the lumbar region in the small of the back. If the nerve supply is damaged in any part of its course, the muscles being supplied become paralysed and are unable to move. It follows that if the spinal cord is damaged, all muscles below the point of damage have been cut off from the brain, and will be paralysed, and this will be permanent because the cord cannot be repaired. Damage to the nerve pathway *after* it has left the cord can often be repaired. Permanent paralysis is only one of the consequences of cord damage, since there is another whole series of nerves running in the cord which carry sensations from all parts of the body to the brain. Therefore there will be loss of sensation as well as paralysis below the point of injury.

It is emphasised that fracture of the spinal bones can occur without damage to the cord taking place. It is when these bones move one over the other, or "dislocate," that permanent cord damage occurs. It is therefore extremely important that cases of back injury be moved

very carefully indeed in order to avoid such a disaster, and special ways of moving such patients are taught in First Aid classes.

Haemorrhage and Shock.

Every part of the body must have a blood supply, or else it will die. It is possible to stop the blood supply to a leg, for example, by fastening a wide rubber bandage tightly around the top of the thigh. This so-called " constrictive bandage " is still mentioned in First Aid books as a desperate means of controlling haemorrhage in a limb. It should hardly ever be used, because by stopping all circulation of blood, the entire limb will die in the course of time. Besides, most haemorrhage can be stemmed by direct pressure on the bleeding point. The tissues of the leg, such as its muscle and skin and bone will begin to die in a little more than half an hour after cutting off the blood supply. The brain, however, will begin to suffer within three *seconds* of its blood supply being cut off, and will die in about three minutes. Thus it can be seen that some parts of the body are more susceptible than others to a failure of the blood supply and the brain suffers earliest of all. Since the brain is where most of the vital functions of the body are controlled, it follows that a shortage of blood to the brain is likely to lead to a " depression of the vital functions "—a state of affairs known to First Aiders as "'shock."

Shock occurs in a number of conditions, but is always due to a failure of the supply of blood to the vital functions of the brain for one reason or another. Its usual causes are:

(1) haemorrhage, when there is a general shortage, but the brain feels it most;

(2) severe burns, in which much fluid is lost from the blood as will be seen later; and

(3) certain medical conditions causing acute heart failure in which there is a failure to pump blood to the brain because the pump has failed.

The treatment for shock consists basically of restoring the blood supply to the brain, and where it is caused by loss of blood or other fluid, the treatment is transfusion. Finally, it must be emphasised that treatment is always urgent, since the brain cannot function for long without its blood supply, and once damaged by the shortage, can never be repaired. No attempt is made here to describe such treatment completely, but the most important things are to keep the head low so as to reduce the work the heart must do to drive blood to the brain; and to avoid artificial heating of the body by hot water bottles, etc., which only diverts blood away from the brain where it is needed, into the skin where it is not.

The treatment of severe haemorrhage is to stop the bleeding, usually by firm, direct pressure, and then to remember above all things that even though the bleeding has stopped, there may be a dangerous state of shock from which the patient could die. This can only be prevented by restoring the circulation to the brain, usually by transfusion; so, having stopped the bleeding drive him fast to hospital for the second part of the treatment which may be as necessary to save his life as the first.

There is great confusion over the use of the word " shock." In the lay mind it is a shake-up of the nervous system caused by a fright, or some bad news, or the sight of something nasty in the woodshed. Even in the medical mind it is sometimes confused, and some of the First Aid books confuse it still further. Too frequently they give the treatment as " loosen all tight clothing from neck, chest, and waist; reassure the casualty and ensure a good supply of air." All this, together with grandmother's hot strong sweet tea is perfectly good enough if the patient is only " shaken-up " by a fright or a fall, but it will be dangerously negligent and time-wasting if he is suffering from true shock due to a failure of blood supply to the brain.

Fainting is a special case which can be prevented by keeping the head low in those who feel faint. It is usually self-curing due to the patient automatically falling into a position in which the head is low. If the faint, however, is due to severe blood loss, this is the same as shock in our proper meaning of the word and must be treated accordingly.

Haemorrhage can therefore be a difficult problem. It is even more so when it is internal. This may be in *medical* cases such as in occasional cases of peptic ulceration in which the blood will be vomited and also passed in the stool. Or it may be *surgical*, in the sense of being caused by injury to internal organs. The blood may emerge from one or other of the various orifices of the body, or it may be entirely concealed within the body. Rupture of internal abdominal organs such as the spleen, kidney and liver can occur with surprisingly little to show in the way of external injury. A fractured thigh bone can pierce the main artery of the leg and cause lethal internal haemorrhage without a drop of blood being visible. In all these cases diagnosis is urgent, followed by emergency blood transfusion if the brain, and hence the patient's life, is to be saved.

Means of detecting the presence of severe haemorrhage without seeing any blood are taught in First Aid Classes as the Signs of Haemorrhage. They are in fact manifestations of the reaction of the body in its attempts to save the failing brain, and are therefore the same as the signs of shock. The main ones are a rapid, feeble pulse getting more rapid and more feeble as time goes on in a desperate attempt to get the remaining blood to the brain; skin pallor caused by constriction of blood vessels near the surface so that the blood which remains is shunted to the brain away from the less vulnerable skin; and finally just before death, restlessness and air hunger.

A word of warning about the First Aid treatment of shock due to heart attack (coronary thrombosis). These patients must be transported at complete rest, but many of them react very badly to being made to lie down, since they have great difficulty in breathing in this position. Transport them relaxed, in a sitting position supported by a large comfortable back rest.

It cannot be too strongly emphasised that with haemorrhage and shock, as with so many First Aid emergencies, the importance of protecting the brain is paramount.

Asphyxia.

The previous section was concerned with maintaining an adequate supply of blood to the brain. This is needed in order to supply the brain's only possible fuel—glucose—and the oxygen with which to burn it. Many different circumstances can conspire to reduce the oxygen content of the blood, and the result in each case is asphyxia. Normally, air is taken into the lungs through the air passages and brought into contact with all the circulating blood. It diffuses from the lungs into the blood, where it enters into a special relationship with the pigment of the red cells—haemoglobin. At the same time, the waste gas carbon dioxide enters the lungs from the blood and is breathed out. The revitalised blood is passed through the heart to build up sufficient pressure to drive it into all the tissues of the body and in particular into the brain. A special system in the brain—the respiratory centre—controls the complicated machinery of respiration and is itself, of course, kept alive by the products of the very mechanism it controls. This mechanism consists of all the muscles of respiration—those which lift the ribs, the diaphragm and many other so-called accessory muscles. They all have to be finely co-ordinated by means of nerve impulses which begin in the brain, pass down the spinal cord and out to the muscles. Information of many kinds comes along sensory nerve pathways to the respiratory centre so that breathing can be automatically adjusted to the changing need

of the moment. In order that life may continue there must be:

(1) a functioning breathing mechanism to revitalise the blood; and

(2) a circulation to carry the revitalised blood to the brain and other tissues.

In many cases when breathing stops and unconsciousness supervenes as brain function is depressed, the heart will go on beating for some time longer. The aim of First Aid is to restore the breathing by artificial respiration *before the heart stops*. Once the heart stops—and it eventually does so abruptly and without warning—the brain is dead within the usual few minutes unless *both* the heart and the breathing are restarted; and this is a very much more difficult proposition than artificial respiration alone.

For these reasons, a patient whose breathing has stopped must have it started again without any delay. Here, as in the case of severe haemorrhage, it is no use telephoning the doctor or even putting the patient in an ambulance. The First Aider must act himself, because he is on the spot and the only one in a position to save life. Both actions require elementary First Aid training, and even school children can accomplish them if they have been well taught.

Asphyxia is the name given to a failure of the oxygen supply to the brain and is due to a breakdown in some part of the complicated breathing mechanism outlined above. One of its chief causes is a blockage of the airway by (*a*) solids or (*b*) liquids. Any foreign body of the right shape and size will block the airway, as also will the tongue in the unconscious patient. Remember how much more easily the child's airway can become blocked because it is so much smaller. Blockage by a liquid, is of course, drowning. Remember that if a patient drowns in the entire ocean, it is only about half a cupful which is doing him any harm—as it only takes this amount to fill the airway. The same goes for the amount of tea, or vomit, required to kill an unconscious patient if it gets down the " wrong way "—as it will unless someone prevents it.

Another very common cause of asphyxia is carbon monoxide poisoning. Carbon monoxide is a lethal component of car exhaust fumes, incompletely burning and badly ventilated fires and stoves, and domestic coal gas. One of the inconvenient properties of haemoglobin is that it combines with carbon monoxide very much more eagerly than with oxygen. Prolonged contact with even a very slightly contaminated atmosphere can build up a concentration of carbon monoxide in the blood which will prevent the blood from carrying sufficient oxygen—and this is in fact how it kills. It takes a very short time for this to happen if the atmosphere is heavily contaminated. Remember the danger of even a very slight leak of the gas either in the kitchen, or into a car from a faulty exhaust pipe or silencer. Many elderly people die of coal gas poisoning every day because their sense of smell is poor and they do not detect the leak.

Other causes of asphyxia are lack of oxygen in the atmosphere, as occurs at high altitudes; crushing of the chest so that the ribs cannot move; paralysis of the muscles of breathing by interference with their nerve supply, usually in First Aid, as a result of a broken neck and consequent damage to the spinal cord (poliomyelitis can occasionally produce the same effect by attacking the nerves just before they leave the spine); and depressing the respiratory centre in the brain, most commonly nowadays by barbiturate poisoning.

The only really effective method of artificial respiration, which all members of any civilised community should be able to carry out, can be learned in half an hour at a good First Aid class. This is the direct, mouth-to-mouth method, sometimes dramatised by journalists as the " kiss of life." The method is taught with the aid of models and cannot be satisfactorily learned by only reading about it.

In discussing asphyxia, we have again had to consider the particularly vulnerable situation of the brain.

Fractures.

Broken bones are not the most serious possible consequences of injuries causing fractures. It is usually more to be feared that further damage will be done by the broken ends of the bones to tissues and organs in the neighbourhood of the fracture. The First Aid treatment of immobilising the part before transporting the casualty is designed to avoid this.

Six types of fracture are commonly taught, but some of them may co-exist in the same injury and the division is only for descriptive purposes. In addition there are two special fractures of the skull.

A " simple " or " closed " fracture is where only the bone is broken, without damage to surrounding tissues and without a wound. A " compound " or " open " fracture is one in which air, and hence germs, can get at the broken bone. This may be through a wound, in whose depths lies the broken bone; or the bone may have been pushed out through the skin; or a bullet track may lead down to the fracture. All these are examples of compound fracture and the great danger is that the bone will become infected. Even now that infections are less feared than before the days of antibiotics, it is still a grave matter for bone to get infected. However the antibiotic is given, we rely on the blood supply to carry it into the infected tissue, and bone has only a very small blood supply. If the infection is not successfully treated it can smoulder for a long time and become a " chronic osteomyelitis " which might ultimately necessitate amputation of the limb—and all because the original fracture was compound or open.

A " complicated " fracture is one in which the broken ends of the bone have damaged some important organ or tissue in the region. For example, a complicated fracture of the ribs is one in which the lung tissue, close behind the inner surface of the rib, has been pierced, and the patient will be coughing up small amounts of bright red, frothy blood. A " comminuted " fracture is one where the bone is broken into several pieces, and an " impacted " fracture is one in which the broken ends have been driven into each other and are firmly impacted. Finally a " greenstick " fracture occurs sometimes in children because their bones are not brittle and do not always break clean across. They partly break like a green stick.

" Depressed " fracture of the skull is where the vault of the skull has been struck and dinted. Many problems arise, since the brain is inevitably compressed and no dressing of the accompanying wound should be allowed to press on the brain. The dangers of infection here are not only to the broken bone, but to the meninges covering the brain, causing meningitis.

Fractured base of skull often passes through that part of the base through which the internal ear channel runs. Thus it frequently results in blood, or cerebrospinal fluid, or a mixture of both, emerging from the ear. The gravity of this fracture lies in the severity of the impact necessary to produce it, which will probably have also caused great destruction of delicate brain tissue. The outlook is usually very poor.

Remember that most casualties with fractures will require a general anaesthetic on arrival in hospital so that their fracture can be set in plaster or otherwise treated. Avoid giving them things by mouth such as drinks, which will mean a three-hour wait before anaesthetic can be administered.

Burns and Scalds.

The severity of a burn or scald depends largely on its surface area. If a patient dies of a burn, the cause of death is either infection or shock,

the latter being due to fluid loss from the surface. Both hazards depend on surface area, since the bigger the surface the more germs are able to enter, and the more fluid can be lost. It follows that the small burn on the hand or arm is seldom a threat to life, however deep the injury; and we shall therefore confine our attention to the larger burns of the whole surface of the limb or trunk. Smaller bodies have a relatively larger surface area, and so a burn of the surface of a child's limb or trunk represents an even greater risk from fluid loss than a corresponding burn in the adult. Everyone has seen the fluid form in the blister of an ordinary small burn. It comes from the fluid part or "plasma" of the blood stream and the loss into such a blister may amount to a thimbleful. This will not hurt anyone. But the loss of similar fluid from the surface of a large burn may amount to many pints. The resultant shock will be partly due to this fluid loss from the blood stream resulting in a reduction in blood supply to the brain. Thus shock from burns has common features with shock from haemorrhage, and it is treated similarly, by transfusion. This time it is not a transfusion of blood but of plasma or some plasma substitute. In practice it is not only water that has been lost but a number of important chemicals dissolved in it as well, so that transfusion solutions have to contain sufficient of each individual substance to restore the deficit. The arrangements for replacing the lost materials are complex and urgent; every bit as urgent as after a haemorrhage and for the same reason. The brain cannot be left too long in need. In general, the First Aid treatment of burns of large surface area is to keep them clean with a dry dressing and get them very quickly to hospital. Life-saving treatment by transfusion cannot start until they arrive. The only permissible delay is in the case of burns caused by corrosive chemicals which must be thoroughly washed off before transport, so that they do not continue to burn the patient on the way.

Unconsciousness.

It is not sufficiently appreciated that the dangers of being unconscious can often far outweigh the dangers from the cause of the unconsciousness. For example it is known that as many as half the deaths from head injuries are due to the airway becoming obstructed and not to the injury itself. The most important thing in managing the unconscious patient from any cause is to preserve an airway. Particularly if the patient is lying on his back it is likely to get blocked:

(*a*) by his own tongue as the lower jaw sags backwards;

(*b*) by his dentures (so remove them);

(*c*) by vomit; and

(*d*) by anything anyone may be tempted to give him by mouth.

Nothing whatever should be given by mouth in any circumstances to the unconscious patient, since he cannot swallow and it will inevitably go into his lungs.

Many of these dangers can be very much reduced by not having him on his back. Place him instead in the semi-prone position: half on his side, half on his front, with the upper leg drawn up to prevent him from rolling about. In this position the head will be inclined downwards. The jaw will tend to sag forwards and the tongue with it, away from the back of the throat. Any vomit will also come forwards. If the tongue does get in the way of the breathing the airway can usually be cleared by bending the head backwards as far as it will go and pushing the whole lower jaw forwards, by pushing from behind the angle of the jaw on both sides.

DRUG ABUSE AND DRUG DEPENDENCE.

This section of earlier editions of *Pears* was simply called "Addiction." This word is still much used, but is gradually being replaced by the terms in the present title, because ideas abou the nature of the problem and methods of dealin with it are changing. Addiction is a word th conjures up rather 19th century ideas in the minc of readers: opium dens, inscrutable oriental Sherlock Holmes injecting himself with cocaine— basically a phenomenon of foreign origin, rathe frightening if its implications were not literar rather than factual, and not of great significanc in Great Britain.

Drug Abuse.

It is now realised by doctors, research scientist social workers, and the police—if still not b society as a whole—that the truth is quite differen The *abuse* of drugs in this country is at presen of large proportions, increasing rapidly and sho ing no signs of diminishing. It is responsible eac year for thousands of deaths by suicide and b accidental overdosage; for an enormous b virtually unmeasurable amount of private suffe ing; and for the loss to society, in terms of reduce working efficiency, of millions of man-hours eve year. It has nothing to do with opium smokin which was never in any case more than th eccentricity of the few. Opium is virtual unused in medicine these days and the amou of smuggling, always small, is now negligible. Th problems today arise chiefly from the misuse drugs given by doctors for their effects on th central nervous system—the pain-killers, sleepin pills, "stimulants," and "tranquillisers."

Drugs and Medicines.

To the doctor, any substance is a drug that ca be introduced into the body from outside, an that is capable of producing some detectab effect. Most such substances have a benefici use. They are "medicines," and as such a given by doctors in suitable cases. Others, f example, nicotine (in cigarettes), alcohol (beer, wine, or spirits), and carbon monoxide (coal gas), are of doubtful benefit and of certa harm and are used by doctors, if at all, only und certain very special and usually experiment conditions.

Medicines may be classified under four ma headings. First, there are those like quinin or penicillin and other so-called antibiotics, th actually cure diseases by eradicating the organis (bacteria or other parasites) that cause disturban of normal bodily function. Second, drugs suc as insulin or the steroids overcome in the u healthy the lack of some necessary substance healthy body manufactures for itself: they mu usually continue to be given for life. Third a the drugs which relieve the signs of disease—f example, there are many new drugs that low the blood pressure or increase the output urine—without being able to put right the di turbed basic situation which is the cause of th trouble. Fourth are drugs to relieve the patien symptoms—which make him feel better, le breathless, take away his pain, help him to slee and so on—although we seldom know why the are able to do this. Indeed, in many cases w suspect that they are acting mainly as a tok of help from doctor to patient, and so encouragin his body to fight a more successful battle on i own behalf. (There is in fact a fifth class of drug which includes the majority of those on th market at any time, the members of which a devoid of any action whatsoever except that enriching those who manufacture and sell them but we are not concerned with these at th moment. They constitute a related, but differen kind of problem.)

There is no doubt that the genuine advanc in beneficial drugs during the last thirty yea have been enormous; but the very successes the penicillins, tetracyclines, antimalaria hormones, and so on have bred in the public an in the medical profession itself an attitude of u critical wonder. There have been relatively fe drugs in the first and second categories mention above: and in the field of mental health, th importance of which is now so rightly emphasise there are virtually none. Yet drugs which a

upon the brain are often received as if they were curative although they may pose fresh problems rather than solve the old. Thus, although there are many drugs which act upon the mind, few do this in any fundamental sense: they relieve pain and anxiety, bring sleep and lessening of stress, and may allow the patient to recuperate himself during the relief they provide. But often this deeper change does not occur—sometimes because the doctor has not clearly seen his part in helping to bring it about—and then the symptomatic relief may come to be sought for its own sake.

New and old drugs are still prescribed for their effects upon the mind—less so now than even a few years ago, before the thalidomide disaster—without sufficient attention to possible long-term dangers, of which there are in effect four.

Dangers of Long-term Medication with Drugs acting on the Brain.

1. *Toxic effects.* Drugs which act upon the nervous system, like any others, have characteristic toxic or unwanted effects of their own (incidentally, these may become apparent rapidly; even, on rare occasions, after only a single dose). Such effects may have little or nothing to do with the desired effects for which they are being prescribed and taken. For example, it has only come to be realised quite recently that aspirin is liable to cause bleeding, which is occasionally serious, from the lining of the stomach in a large proportion of people who take aspirin regularly; or that phenacetin, another substance very frequently present in pain-killers that can be bought from chemists without prescription, leads (after prolonged use) to kidney damage. Some drugs may cause rashes and other allergic reactions in susceptible subjects; and jaundice, fainting, tremors, and motor disorders are known to occur in some patients taking a variety of other drugs.

2. "*Rebound.*" The body works in such a way, over a variety of its activities, that it tends to return to a "neutral" position after it has departed from this for any reason. For example, over-eating tends to be followed by a lessening of appetite, at least for a time; the runner makes up for his air-deficit during the race by breathing more deeply thereafter; and if, at rest, you breathe for a time more rapidly and deeply than you need, this period will be followed by one in which you breathe *less* often than usual until the balance is restored. These illustrations—and there are others—have nothing to do with drugs: but in a similar way, it seems that if a continued pain, or an unpleasant emotional state such as anxiety or depression is changed into its opposite, or removed altogether by the use of a drug, the prior state may return with increased force when the drug is no longer taken. The "rebound" phenomenon, naturally, encourages the patient to take another dose, and so on.

3. *Habit formation.* This alternation of mood-changed-by-drug with the disturbed mood itself leads to the habit of taking the drug. The patient comes to rely upon it and to take it anyway, even before the unpleasant state has returned. At this stage he is said to be "habituated": he has a psychological need for the drug, and later may become disturbed at the possibility that it will not be available when he needs it. This might not matter so greatly, if it were not that continued use of drugs in this way has physical consequences as well.

4. *Tolerance and habituation.* The body also tends to restore its own balance when drugs are given, too. It "learns" surprisingly quickly how to deal with substances with which it has never before been confronted, so that it eliminates subsequent doses more and more quickly and completely. Thus the effect of each successive dose is smaller and lasts for progressively scorter periods of time. To counter this, the patient tends to increase the dose: and the vicious circle continues. At this point he has become physically dependent upon the drug: and he may suffer physically—sometimes so severely that he dies—if supplies are not continued.

As he increases the dose in this way, so his tolerance of its effects increases, to such an extent that after prolonged use he may be taking doses of a drug that are five or ten times greater than those which will kill somebody not dependent upon them in this way. It sometimes happens that a patient develops a renewed craving at some point after a course of treatment, in which the dose of drug has been reduced without removing the underlying cause of his dependence. He may then obtain and use the dose he habitually took before treatment, not knowing that his body will have lost its tolerance of such doses. That dose is now as high for him as for any other person and so may be lethal. There has been a number of deaths for this reason.

Factors in the Causation of Dependence.

The risk of becoming dependent upon a drug is governed by three main factors: the drug itself, the personality of the individual who takes it, and the circumstances in which it is taken. Most adults have taken alcohol at one time or another, unless it is against their code to do so; yet *relatively* few are dependent upon it (relatively few, but many too many: perhaps half a million in the United Kingdom alone). Many of us have had morphine or some other strong pain-killer for medical reasons, without becoming dependent upon it (whatever so-called addicts say, it is extremely rare for anyone to become dependent on an opiate because he was introduced to it in a medical setting). On the other hand, if we start to take such a drug "for kicks"—as more and more people, particularly teen-agers and young adults are doing—it is extremely probable the we shall become dependent upon it, and sooner rather than later at that. It is also probable that each one of us would become dependent, were he obliged to take it regularly, for long enough, and in sufficient dosage. Thus, although there are personalities—psychopathic, immature, or unstable—that are more prone than others to become dependent if they are exposed to the drug, there are also drugs that are more likely than others to cause such dependence no matter to whom they are given. The extent of the dependence will vary: with some, it is never physiological but remains psychological (but not the less real or disturbing for that). Also, the rate at which dependence develops may vary; and the picture presented by the dependent subject—the extent to which his normal life is impaired, or to which he becomes dangerous to himself or others—varies as well. In a very much oversimplified way, some of these relationships will now be summarised for certain substances.

Heroin, morphine and cocaine are usually injected. Barbiturates (sleeping pills) and Amphetamine ("Benzedrine") are tablets or capsules, and Marihuana ("reefers," hashish) is smoked in cigarettes. Heroin and cocaine are now usually taken together. Combinations of drugs often act differently from their individual constituents and patients dependent upon them are even more difficult to treat. Barbiturate and amphetamine, also, are often mixed (as in "purple hearts"). There is considerable *psychological* dependence on heroin, morphine, cocaine, and amphetamine, but much less with marihuana. *Physiological* dependence is great with heroin and morphine, less with barbiturates, alcohol, and amphetamine in that order, and virtually nil with cocaine and marihuana. Personality plays a greater part in initiating dependence on alcohol, marihuana, and barbiturates than with the others. Heroin, cocaine, and morphine are the cause of more antisocial tendencies in dependent people than alcohol, barbiturates, and amphetamine. The chief danger of marihuana (mere possession of which is illegal) seems to be that the search for it will lead the searcher into localities where his risk of exposure to even more dangerous influences is greatly increased. It is thus some-

times argued that if it were legal to consume marihuana, the number of young people who yearly become dependent upon the other more dangerous drugs would in fact decrease. There is as yet no evidence for or against this proposition. The number of drug dependent people in U.K. is rising fast for heroin and cocaine. This number is very large for alcohol, and is increasing in the case of barbiturates and marihuana. Very few people are dependent on morphine, and the number is not growing.

Treatment.

Exhortations, imprisonment, and other moralistic or legalistic approaches are useless. Treatment of any person dependent upon a drug is a matter for a qualified psychotherapist. It is liable to be time-consuming and frustrating for patient and doctor, and it is frequently unsuccessful. At present, there are too few specialists or centres where treatment can be obtained, although it is to be hoped that this situation will change as the problem is increasingly seen by our society to be of exceptional gravity.

When there is little or no chance of cure, prevention is certainly the best treatment. Drugs should only be taken on the prescription of a doctor: and the patient should remind him from time to time, if this be necessary, that he would like to dispense with his drugs as soon as the doctor thinks it possible. It should also be remembered that there is often no need to reach for the aspirin (or any other drug that anyone can buy from the chemist without prescription) at the first sign of a headache—or to reach for it at all to help one sleep or relax, for which purpose such drugs are in any case pharmacologically useless. A wait for ten minutes is good discipline, and will frequently resolve the problem to an extent that makes a drug unnecessary.

DISEASES OF THE BLOOD

INTRODUCTION.

There are about eight or ten pints of blood in the adult human body. Its main function is to transport nutrient materials to all the various tissues and to carry waste products of tissue activity to organs such as the lungs, kidneys, and liver for disposal. It also helps to maintain a constant chemical environment for the body cells, some of which would be very disturbed in their function if the correct balance of organic and inorganic chemicals were not maintained. The blood also serves a protective function in fighting disease, either with certain of the white cells, or by means of immune antibodies dissolved and carried in the plasma.

A little more than half the volume of blood is the fluid plasma, in which are dissolved all the nutrient materials, organic and inorganic chemicals, hormones and large quantities of protein. The remainder consists of red cells, white cells, and some particles which are not really cells, called platelets. In every cubic millimetre of whole blood, or in every droplet the size of a pin head, there are about 5 million red cells, between 5,000 and 10,000 white cells, and 200,000 platelets as well as half a cubic millilitre of plasma. The red cells suffer a great deal of wear and tear as they are hurled round the circulation, and they only survive for three or four months. There is a red cell factory in the bone marrow which replaces them at exactly the rate they are destroyed, and you have made very many millions of new ones while you have been reading this single paragraph. The function of the red cells is to carry the oxygen from the lungs to the tissues, and to play an important part in carrying the waste gas, carbon dioxide, in the reverse direction. A shortage of red cells, and hence of their oxygen-carrying pigment, hæmoglobin, is called anæmia: an excess is called polycythæmia.

There are five kinds of white cells or leucocytes: neutrophils (or polymorphonuclear leucocytes), eosinophils, basophils, lymphocytes, and monocytes. The first three are quite actively motile like amœbæ, and are capable of ingesting bacteria and other particles by "phagocytosis." There is a great increase in the number of neutrophils (a leucocytosis) during bacterial infections and other inflammatory conditions like appendicitis. Eosinophils are found in larger numbers than usual in allergic conditions like asthma, and in infestations by worms and other parasites, but we do not know why this should be. Lymphocytes are concerned with the manufacture of antibodies. In some infections, particularly tuberculosis and viral infections, there are fewer white cells than usual (leucopenia). Pus consists of the dissolved remnants of inflamed tissue and many dead neutrophils which have become casualties in the battle against infection. It also contains surviving bacteria, and as such is a source of further infection.

Platelets are curious particles, smaller than any of the cells. They are little pieces broken off certain special bone-marrow cells which produce them. They have a role in the stemming of blood loss after injury, partly because they are sticky and adhere to one another and to broken blood vessels and help to plug the open ends of damaged vessels; and partly because they contain a great deal of a substance (thrombokinase) which is necessary to the clotting mechanism of the blood.

Hæmatology, as the study of blood and its diseases is called, is a very complicated subject and only a brief general account will be given here. Diagnosis is usually made by taking small samples of blood (or of the bone marrow where blood cells are made), counting the numbers of the different cells and examining their appearance under the microscope. We shall briefly consider the main diseases involving red cells, white cells and platelets.

Red Cell Diseases.

These are of two main groups leading to a shortage of red cells (anæmia), or an excess (polycythæmia). The former is much the more common and there are many different kinds. In all of them the shortage of red cells results in a depletion of the capacity of the blood to carry oxygen. This means that the heart must work harder to send more blood than usual to the tissues, and even so the tissues will often go short. The patient will be persistently tired and listless, and if the anæmia is severe the action of the brain and heart will be seriously impeded, even leading to fainting, cardiac pain, and breathlessness on exertion. All these symptoms, however, can be caused by many other conditions. The only way to be sure they are due to anæmia is by a proper examination of the blood, and even this will not lead to the truth if the picture has been spoilt by the patient taking iron tonics and other remedies of his own accord. Therefore do not dose yourself with tonics, in case you really have anæmia. You may make it impossible to arrive at a proper diagnosis later.

Hæmorrhagic Anæmia. Anæmia, a shortage of red cells, may be due to a variety of causes, singly or in combination. One very obvious cause is loss of blood, or hæmorrhage. Following the sudden loss of a pint or two of blood or more, the red cell-producing bone marrow "factory" will step up its production; but even if it is adequately supplied with all the raw materials such as iron it may well take many weeks to build up the numbers to normal. A very severe degree of hæmorrhagic anæmia is usually treated by blood transfusion. Milder degrees can be treated by taking extra iron, often over a long period of time. The supply of iron for making new red-cell pigment is nearly always the bottle-neck which limits production. Hæmorrhagic anæmia can commonly occur, however, without a sudden severe hæmorrhage. From what has been said about the constant replacement of red cells as they wear out it must be obvious that even if there is only a slight failure to keep pace with the numbers lost, severe

months of such a failure can eventually deplete the numbers to the level of very severe anæmia. This situation is common when small amounts of blood are being continuously or repeatedly lost, and here again it is a shortage of dietary iron which is the usual cause of the failure to replace the lost red cells. Normal menstrual loss in women and girls whose diet is on the border-line of iron deficiency is a common cause of progressive tiredness and lack of energy. Where the menstrual flow is heavier than usual, or where it is frankly excessive in older women due to the various common gynæcological disorders, serious anæmia is surprisingly common. During pregnancy a great deal of iron is lost by the mother to the baby, and this, together with the inevitable blood loss at delivery, often makes for a very tired mother indeed, just at the time when there is an enormous amount of work to be done to manufacture milk and attend to all the extra household tasks of baby care. For these reasons it is almost routinely advisable to build up stocks of iron throughout the pregnancy by remembering to take the pills provided. Men as well as women can lose small amounts of blood continuously in later life from gastro-intestinal conditions such as piles, ulcers, and tropical infestations such as hookworm; and here again the anæmia may be just as severe in the long run as that which inevitably follows a sudden, massive hæmorrhage. One extra word of warning. Do not assume because you are pale that you are anæmic. Pallor is a very poor guide, because it is dependent on so many other things, like the blood vessels in your skin, and its thickness and translucency. Nothing but a blood test (which is so easy for your doctor to do) can really tell you if you are anæmic. And if your anæmia is due to a blood-losing condition, then that too must be treated. So do not be tempted to treat yourself, and never delay seeing your doctor about any excessive or unexplained bleeding, from any source.

Hæmolytic Anæmia occurs when for any reason, there are more blood cells than usual being destroyed in the body. This may be because the cells are abnormally fragile, or because normal cells have been attacked by something to which you are allergic, or rarely because you have become sensitive to your own red cells. Sometimes unborn babies have severe hæmolytic anæmia, due to an incompatability of blood group (Rh factor) between the mother and the baby, and the same sort of thing happens if incompatible blood is given by mistake in blood transfusion. Up to a point, in mild hæmolytic anæmia, the bone marrow can keep pace with the increased loss of cells, but beyond this point anæmia develops. After incompatible blood transfusions a very dangerous situation results from the effects of the destruction of red cells and the liberation of their products into the blood. One form of jaundice is often produced in hæmolytic anæmia, the patient becoming yellow because of the breakdown products of red cells circulating in excess as bile pigments. These latter are normally always present to a small extent due to the normal, comparatively small, rate of destruction of effete red cells

Aplastic Anæmia is the term given to anæmia due to a virtually total failure of the bone marrow red-cell factory. Sometimes this occurs for no obvious reason. It is sometimes due to a heavy dose of radioactivity or X-rays knocking out the cells of the "factory." It may even be due to cancer cells growing in the bone marrow cavity and not leaving sufficient room for the red marrow cells. It is fortunate that aplastic anæmia is very rare, because it can only be treated by blood transfusions every few weeks for the rest of the patient's life. Very occasionally there have been exceptions to this rule, when the patient's marrow has re-awakened for no apparent reason and suddenly begins to make red cells again.

Pernicious Anæmia. This is a fairly uncommon anæmia, which has a very interesting story. The processes by which red cells are manufactured are many and complex, and depend, like so many other bodily activities, on the supply of a vitamin containing cobalt, called vitamin B_{12}. This is nearly always present in more than adequate quantities in the diet, but in order for it to be absorbed from the intestine, there must also be a substance called "intrinsic factor" which is normally made by the lining of the stomach. People with pernicious anæmia have suffered a degeneration of the lining of their stomachs, probably because, for some reason, they have become "sensitive" to this part of their own tissue. This kind of civil war within the body is known as an "auto-immune" disease, and is comparable in type with some forms of hæmolytic anæmia. In other words they destroy their own stomach lining, fail to produce "intrinsic factor," and as a result fail to absorb vitamin B_{12} into the body. Faced with a failure in the supply of this essential substance, the bone marrow produces too few red cells, and the few that are produced are deformed, much too large, and very fragile. In addition to its role in blood formation, vitamin B_{12} is essential to the normal functioning of the spinal cord, and in long-standing cases of untreated pernicious anæmia, there is often a resulting neurological disability.

The cure for pernicious anæmia was discovered about forty years ago, and is a triumph for the scientific investigation of the causes of disease. While treating anæmic dogs, an American scientist named Minot discovered that eating raw liver in large quantities produced a tremendous improvement. Patients with pernicious anæmia were then made to eat vast quantities of raw liver—about one or two pounds a day—and were found to get better, whereas previously they had inevitably died. Raw liver is, of course, very unpleasant to eat, and after a few years it was found possible to prepare crude extracts for injection. Injection had the great advantage that no absorption difficulties arose, and much less liver could be used. Biochemists then began the enormous task of trying to find which of the thousands of substances in liver was the vital factor, and after many years of painstaking chemical fractionation of liver and trying out the various fractions as a cure for the disease, vitamin B_{12} was discovered. The pure substance is one of the most powerful substances known, being active in amounts as small as millionths of a gram. Nowadays pernicious anæmia is treated by small occasional injections of the vitamin, whose other name is cyancobalamin.

Polycythæmia. Too many red cells per cubic millilitre of blood can be found without there being an increase of the total number of red cells in the body. This occurs in dehydration, when there is a loss of plasma without a comparable loss of cells, and is called hæmo-concentration. Alternatively, the bone marrow can manufacture more cells than usual as a response to living for long periods at high altitudes. The beneficial result can be that the blood can carry normal amounts of oxygen, even though the supply (in the rarefied air) is reduced. Finally there is a red cell disease, analagous to leukæmia (*q.v.*) in which the bone marrow factory gets out of control and produces too many cells with no beneficial results. The number in the blood can be double the normal and the blood becomes so thick that the heart has difficulty pumping it round the body. This disease (*polycythæmia rubra vera*) used to be treated by repeatedly bleeding the patient to reduce the numbers. It is now treated very successfully with carefully judged amounts of radioactive phosphorus or certain other "anti-mitotic" chemicals which reduce the rate of multiplication of bone marrow cells. Care has to be taken not to knock them out altogether, in which case aplastic anæmia or agranulocytosis (*q.v.*) could result.

White Cell Diseases.

These are fortunately much rarer than diseases involving red cells, and are usually much more to be feared.

Agranulocytosis. In this condition the number of those white cells which are responsible for phagocytosis of bacteria falls precipitously. The result is that one of the main bodily defences against infection fails, and the patient may die from an overwhelming invasion of germs and the accompanying high fever. The usual cause is abnormal sensitivity to certain drugs, often those which are in widespread use and only give trouble in the occasional case. One example among hundreds is the antibiotic chloramphenicol which specifically kills typhoid bacteria, and is used for that purpose. It is believed that about one case in 60,000 becomes sensitive to it and agranulocytosis often fatally follows. The fact that almost any drug *can* do this to some people and yet be quite safe for the majority, is one good reason not to dose yourself unnecessarily with over-the-counter medicines.

Leukæmia. This is a cancer of the white cells, in which the normal rate of production of any of the white cells gets out of control, leading to a pile-up of abnormal cells at the site of production (bone marrow, lymph nodes, and spleen) or in the blood, or both. In spite of an increase in their numbers, their abnormality renders them unable to combat infection; sepsis and fever result. It is known that this kind of cancer can be caused by the effects of ionizing radiation on the white-cell factory, and it is certain at least in animals, that viruses can also be responsible. Survivors from the atomic explosions in Japan have subsequently suffered from leukæmia far more commonly than the rest of us, as have doctors, nurses, and patients who have been over-exposed to X-rays. At the time of writing, leukæmia is still a uniformly fatal disease, although patients may sometimes survive many years. Their remaining time can nearly always be made more comfortable by various forms of treatment, and one day a cure will be found by the research workers devoting their time to its study. It is difficult not to get very impatient with the slow rate of progress of these studies, particularly when caring for children and young people whose lives are inevitably ended by the disease. The solution, however, as with other forms of cancer, probably depends on the understanding of the nature of life itself, and as long as biological research remains short of the relatively small amounts of money required to tackle these problems at reasonable speed, we have no right to be impatient, except with our elected leaders who spend far more than is needed on less important things.

Hodgkin's Disease, Lymphosarcoma, and Reticulosarcoma. These are cancerous diseases in many ways similar to leukæmia, in which the cancer process involves cells of the so-called reticulo-endothelial system. Such cells are principally in lymph nodes (which used to be called lymph glands) and the spleen. Hodgkin's disease is named after one of the more illustrious pathologists at Guy's Hospital who first described it nearly a hundred years ago, and whose early specimens of affected lymph nodes are still preserved there; is an even greater puzzle than leukæmia. There are all grades of severity, and although many patients die within six months, many survive much longer, even for twenty years in some cases.

Hæmorrhagic or Bleeding Diseases.

Whenever blood vessels are damaged by injury, there is a remarkable series of mechanisms which automatically come into operation to stem the flow of blood. There is a constriction of all the smaller vessels in the locality. Platelets stick together and release substances which help the vessels to stay constricted as well as others necessary to blood clotting, and yet others which help to bind the clot tightly together. Later, materials appear to prevent too much clotting, and eventually the clot is removed altogether as healing proceeds. There are some very complicated diseases of this blood-conserving mechanism which can lead to abnormal bleeding, sometimes beneath the skin to produce bruising or even smaller leaks; sometimes leading to a greater loss of blood, particularly following a wound. In some kinds of *purpura* (bleeding tendency) the blood vessels are the cause of the trouble, having become fragile and leaky for a number of reasons. This happens in old age (*senile purpura*), in scurvy, or vitamin C deficiency, as an occasional accompaniment to infective diseases, or as an immunological effect on the lining of blood vessels when the patient becomes sensitised to certain substances (*Schönlein-Henoch* or *anaphylactoid purpura*). The latter often follows a streptococcal sore throat, just as rheumatic fever and acute nephritis do; and as well as the purpura there may be joint pains and nephritis. Just as almost any drug or chemical will cause agranulocytosis in some people, so it can also cause anaphylactoid purpura.

Purpura may also be due to a lack of platelets, known as thrombocytopenia (a shortage of thrombocytes or platelets). This can happen if the bone marrow factory is depressed, since this is where platelets too are made. It is therefore a common accompaniment of leukæmia or aplastic anæmia. Or there can be increased destruction of platelets in some diseases of the spleen. Platelets normally last eight to ten days, but their lifespan can be shortened in heart failure, and following massive transfusions, or often for no apparent reason (" idiopathic " thrombocytopenia), when removal of the spleen can sometimes help.

Finally, defects of the *clotting mechanism* will lead to a bleeding tendency, and since the mechanism itself is very complex, so is the variety of things which can upset it. The liver provides the blood with many of the substances required for clotting, so it is not surprising that a clotting defect commonly accompanies liver disease. One necessary substance for blood clotting is called " anti-hæmophilic factor " and is missing from people who have inherited the disease *hæmophilia*. These unfortunate people may die of hæmorrhage from quite small cuts or minor surgical procedures like tooth-extraction, and although it is possible to prepare antihæmophilic factor, it is not yet possible to give continuous, life-long treatment with it. In emergencies a transfusion of fresh blood (the factor is destroyed by storing) is sometimes used.

DISEASES OF THE HEART AND BLOOD-VESSELS.

INTRODUCTION.

The heart consists of about three-quarters of a pound of muscle, which makes up the walls of its four chambers. Anatomically the human heart closely resembles the sheep's hearts to be found in a butcher's shop. Indeed it would be an instructive exercise to dissect one of these in the order described below, since there is no other way of properly appreciating what the chambers, valves, etc., are really like. There are two quite separate pumps in the heart—one on the owner's right (or on your *left* if you are looking at the front of someone else), and one on his left. The right heart collects spent, deoxygenated, " venous " blood which returns there from the whole of the body, and gives it the comparatively small push required to drive it through the adjacent lungs. The left heart collects the revitalised, oxygenated " arterial " blood as it trickles away from the lungs, and gives it the enormous push required to build up the arterial blood-pressure, so that it can be forced through all the tissues of the body. As may be expected, the right heart chambers have much thinner walls than the left, since their muscle has much less work to do. This will help you get your bearings with the sheep's heart. The tip, or apex, is the lowest part. The thick-feeling side is the left, the thin the right; and the great vessels are at the top.

The upper chamber on the right, or right atrium, has two large openings into it through which all

the spent blood arrives from the upper and lower great veins (the superior and inferior venae cavae). Cut open the thin wall of the right atrium with scissors between these two holes to lay open the interior of the chamber, noting the "auricle" or "dog's ear" that forms a small cul-de-sac. The whole chamber is sometimes, inaccurately, called the auricle. You should be able to push a finger downwards into the lower chamber—the right ventricle—through a communicating hole guarded by the three thin cusps of the *tricuspid valve*. These will not obstruct your finger, since they are designed to permit blood flow in the same direction. When the atrium is full of blood, it squeezes its contents through the tricuspid valve into the right ventricle; and when, a split second later, the ventricle is full and contracts, the three cusps come together to prevent the blood from flowing backwards into the atrium again. Instead the spent blood is driven onwards through the *pulmonary valve* (in the upper part of the right ventricle), through the pulmonary artery, to be delivered to the lungs. The pulmonary valve has three very well-formed cusps which prevent blood from coming back into the ventricle as it relaxes to receive more blood from the atrium before the next contraction or beat. It is possible to pass a blade of the scissors from the opened-out right atrium, through the tricuspid valve towards the tip of the heart, and cut along the right border of the heart through the thickness of the ventricular muscle. Then cut upwards again, passing the scissors blade through the pulmonary valve and open up the *pulmonary artery*. If you have done this successfully you will have followed the path taken by the spent blood through the right heart to the lungs. Note the thick, round bands of muscle lining the ventricle, and notice too that you have not entered the left heart, which has no connection with the right except in some congenital malformations (see later). The same dissection can now be made of the left heart. Open up the *left atrium*, noting its "dog's ear" or "auricle," pass the scissors down into the *left ventricle* through the two rather flimsy cusps of the *mitral valve*. Notice how much thicker is the muscle of the left ventricle, and cut upwards through the three well-formed cusps of the *aortic valve* into the main artery of the body—the *aorta*. The aorta as it leaves the left heart is distinguishable from the pulmonary artery as it leaves the right, partly by the extreme toughness of the aortic wall (it has to withstand so much more blood-pressure); and partly by the entrances or orifices of the two small branches given off by the aorta, just beyond the valve cusps, which go to supply the heart muscle itself with blood. These are the *coronary arteries* which are so necessary for the heart's own survival.

The amount of blood pumped in unit time, or the *cardiac output*, can be varied a great deal, according to the needs of the moment. This is accomplished by altering both the heart rate and the stroke volume, the amount expelled per beat. Every minute, the healthy adult man at rest shifts about ten pints of blood through the heart—an amount equivalent to all the blood he possesses. When exercise is taken, or in response to anxiety or fear, this is stepped up many times, so that the muscles can receive a greatly augmented supply of the materials required for action. The controlling mechanisms which allow these changes to be made automatically are partly organised in the brain by the so-called *cardiac centre*; and partly by local mechanical and chemical stimuli to the heart muscle itself. The cardiac centre is continuously receiving information through nerves about the physical and chemical state of the circulation, and also from the mind; which is partly how certain emotions make the heart beat faster. All the information is integrated, and a cardiac output continuously arranged which is appropriate for current demands.

Cardiac Neurosis. In ordinary circumstances at rest, most healthy people are not conscious of their heart-beat. However, there are many perfectly healthy people whose hearts slip in an extra beat occasionally. Sometimes their owners are aware of this, and become unnecessarily alarmed. Their fear causes palpitations (a pounding of the heart) and the tension mounts. An undue anxiety about the tricks played by a healthy heart sometimes leads people to interpret minor pains in the chest, or even indigestion, as grave symptoms of heart disease, and the consequent anxiety leads to still worse symptoms. If you are one of these worried people, take your worries to your doctor, and let him decide for you whether there is anything wrong. A hundred to one there isn't, and then you will have to find something else to worry about, or better still give up the habit altogether. Many people secretly worry about heart disease and high blood-pressure for years, when very often they are worrying unnecessarily. Even if there is cause for worry, so much can be done for these conditions (as it can for cancer) provided medical advice is taken early in the course of the disease. Remember, too, that the slight feeling of giddiness when you get up suddenly from having been lying down, is often experienced by most normal people; but if you get frightened by it you will begin to breath more quickly and deeply; and this in itself will make you feel even more faint—and so on.

Heart Failure. When the cardiac output of blood is too little for the requirements of the body, a state of *circulatory failure* has arisen, and when this is due primarily to the heart itself being at fault, it is more properly called *heart failure*. As will be seen, heart failure is not a disease, but the common result of a large number of different diseases. The signs and symptoms produced are caused by two sorts of process: (*a*) tissues of the body have too little blood flow through them and are therefore undersupplied; (*b*) blood accumulates and stagnates in tissues, causing congestion, since the failing heart cannot move forward the amount of blood presented to it in the great veins. Often the left or right side of the heart fails disproportionately. In *left heart failure* the lungs are congested because they are the territory from which the left heart is failing to move blood. The patient has great difficulty with his breathing, and in advanced cases may not be able to breathe when he lies down horizontally, because the lungs become so congested and waterlogged. In *right heart failure* the main veins are congested and other parts of the body become swollen with excess tissue fluid, mainly in the lower parts such as the legs and ankles. This swelling with fluid is called œdema, and in heart failure is only partly due to the mechanics of the failing heart. It is mainly due to a poorly understood retention of sodium in the body, a situation in which excess water is also retained. Whatever the type of heart failure, it is always likely to be a changing condition, since the amount of failure will depend as much on the demands being made as on the state of the heart. For instance, in mild cases at rest when the required cardiac output is small, there may be no signs or symptoms. These may only appear on exertion. Heart failure will be referred to again later under the various conditions which cause it.

Treatment of heart failure is quite logical. It is aimed at correcting the imbalance between supply and demand of blood, and at the removal of the accumulated excess fluid. We can therefore (*a*) reduce the body's demand for blood; (*b*) increase the supply or cardiac output; and (*c*) promote the excretion of sodium and fluid. Demand for blood is reduced by rest, both physical and mental, and by reduction of weight, since obesity (being overweight) is an additional demand on the cardiovascular system. The cardiac output can be increased by administering a "tonic" to the heart muscle in the form of *digitalis*, which is a powerful heart stimulant derived from foxglove leaf. Fluid (and hence salt) accumulation can be helped by restricting the intake of salt and by giving drugs which promote its excretion by the kidneys (diuretics). Very occasionally, very large accumulations of fluid in the legs, abdomen, or thorax, are tapped and drained physically, with needles. These remarks on treatment, as elsewhere in the Medical Section, are of course very general and must not encourage anyone to treat themselves for such a potentially serious

condition as heart failure. Even such a simple measure as doing without salt can be practised quite unnecessarily by many people for years, simply as a result of reading a paragraph like the above. The most they accomplish is to make their food taste horribly dull. If you need to reduce salt intake you should be in your doctor's care, and so please let him decide.

Congenital Heart Disease. It has been estimated that of all the babies born who survive at least one month, there will be about one in every two hundred with some form of congenital heart disease; that is to say that the heart will have failed to develop properly in embryonic life. In some cases this is associated with a virus disease of the mother (commonly rubella, or German measles) or with certain drugs taken by the mother (e.g. thalidomide) at a time, very early in pregnancy, when organs are assuming their adult shape. Parents should see to it that their daughters get German measles before they grow up; and drugs of all kinds should be avoided where possible during early pregnancy. In most cases of congenital heart disease, however, there is no known cause, and it seems that the manner of formation of the embryonic heart is so delicate that it can be thrown out of gear very easily, perhaps even by chance. Scores of different types of defect occur, singly and in combination. Any of the valves may be anatomically defective—either failing to close properly (*incompetence*) or being too tight (*stenosis*); the great vessels (pulmonary artery and aorta) may be switched round, or *transposed*, so that they emerge from the wrong ventricle; there may be defects in the wall (*septum*) which separates the atria or the ventricles on each side (*septal defect*, or " hole in the heart "); or there may be a persistence of the vessel which in the fœtus normally by-passes the lungs by joining the pulmonary artery to the aorta (*patent ductus arteriosus*). This vessel normally closes at the time of birth when the first breaths are taken, and subsequently disappears, so that the whole output of the heart is then sent round the lungs. Detecting congenital heart disease early is one of the purposes of routine post-natal check-up examinations of the baby. Exact diagnosis requires very complicated techniques, and sometimes the structural defect can be corrected by surgery, with almost miraculous results.

Rheumatic Heart Disease. Acute rheumatic fever is not to be confused with other forms of rheumatism. Many tissues of the body (particularly the heart) are attacked, as well as the joints, and the trouble is due to a sensitivity which has developed to certain bacteria (*haemolytic streptococci*) which have probably caused a sore throat about three weeks before the onset of the disease. Why acute rheumatism only rarely follows streptococcal sore throat is poorly understood, but this is no consolation to the one per cent or so of the population whose hearts bear its scars. During the acute phase of the illness which usually occurs before the age of fifteen, inflammatory damage occurs to the valves, the heart muscle, and the sac in which the heart lives, the *pericardium*. So there is a *valvulitis* or *endocarditis*, a *myocarditis* and a *pericarditis*. There may be acute heart failure at this stage if the heart is severely affected. The better-known results of rheumatic heart disease, however, are caused in the ensuing years by scarring of the healed valves. The valves are thickened and deformed. They may have lost their elasticity and stretch, so that they do not close properly (*incompetence*); or they may contract and tighten (*stenosis*). In both cases the heart chamber situated next to the affected valve has to work progressively harder, either because it gets no rest in between beats (in *incompetence*); or it has to force the blood through too narrow a hole (in *stenosis*). The end result is some variety of heart failure (P27). Although there are other causes of valvular heart disease which will now be mentioned, rheumatic fever is much the commonest, and much valve trouble can be blamed on rheumatic fever even when the patient has no recollection of ever having suffered from it. The other, much rarer, causes may be syphilis, congenital valvular anomaly, healed bacterial endocarditis, atherosclerosis, and mechanical injury.

The most commonly affected valve is the mitral, usually causing *mitral stenosis*, in which the opening between the left atrium and left ventricle will sometimes only admit one finger-tip instead of three fingers as it should. In time the left atrium becomes much enlarged as it overworks to force blood through this narrow orifice. Later still a back pressure develops in the lungs causing congestion and breathlessness; and even later the right ventricle is strained as it tries to force blood into the already congested lung. This is a classic example of the march of trouble backwards from the site of the damaged valve involving first the chamber " behind " it (the left atrium), then the territory " behind " that (the lungs), then the pulmonary arteries taking blood to the lungs, and finally the right ventricle trying to send blood to the pulmonary artery. This steady march of events is usually very slow, and can commonly take twenty years or longer from the initial attack of acute rheumatism to the severer symptoms of advanced mitral stenosis. Treatment is both medical and surgical. The heart failure is treated medically as already described. These days surgical reopening of the valve is almost commonplace, either by inserting a finger through the left auricle and breaking down the constriction, or by opening up the valve and re-shaping the valve under direct vision. The latter involves the additional problem of by-passing the heart by the use of some sort of external pump and poses additional problems, even though from other points of view it is obviously more convenient. As always with major surgical procedures much of the problem is in selecting the patients who will benefit from the operation and in whom it is feasible. Quite often there are other valves involved, mainly the aortic or tricuspid or both, and the hydrostatic or " plumbing " problems can be extremely complex. With luck, however, combined with good judgement and good surgery, the lives of incapacitated patients can be transformed by mitral, and other valvular, surgery. The *aortic valve* is stenosed or narrowed by other degenerative processes besides rheumatism. *Tricuspid stenosis* is nearly always rheumatic in origin.

Coronary Heart Disease. This is the term used whenever the blood supply to the heart muscle (through the coronary arteries) is reduced to such an extent that the heart muscle suffers from a lack of supplies. It has a number of causes, but the only really common one is partial obstruction of the coronary arteries by a condition known as *atheroma* or *atherosclerosis*, and sometimes inaccurately called *arteriosclerosis*. This arterial disease is described later (P30). It takes the form of swellings or lumps on the lining of the artery which, if they become large enough to interfere seriously with the flow of blood, produce a blood starvation or *ischaemia* of the tissue being supplied. Obviously, the smaller the artery, the more easily will a lump of given size impede the flow. Equally obviously, the greater the demand for blood, as in exercise, the more blood " starvation " there will be. There are two degrees of coronary artery disease: one in which the blood flow is reduced to the point where the increased demands of hard work cannot be met, and this results in *angina pectoris* due to *coronary insufficiency*; the other is when the coronary artery becomes completely blocked, preventing the flow of blood altogether, usually by a *thrombus* or clot of blood, and this is *coronary thrombosis*.

Angina Pectoris. Whenever activity is increased in any muscle, the demands for oxygen and nutriments from the blood-stream increase, and as these are used up there is an increased production of waste products known as metabolites. To meet these demands for a greater supply and a more efficient waste-disposal, the blood flow through the exercising muscle must always be increased. If sufficient increase does

not occur, not only will there be a shortage of supplies, but there will also be a pile-up of metabolites in the muscle which cannot be carried away. It is mainly because of these latter that pain is caused in ischæmic, or blood-starved muscle, and pain is one of the chief symptoms when heart muscle becomes ischæmic. One important mechanism for increasing blood flow normally to exercising muscle is by automatically dilating the vessels concerned. Diseased vessels, such as coronary arteries when they are affected by atheroma, are not so easily dilated, although certain drugs which are powerful dilators of arterioles can accomplish a great deal, albeit temporarily. The measures taken to relieve the pain and blood-starvation of angina are two-fold. The patient can reduce the demands of the heart by a few minutes' rest, and a drug (usually nitroglycerin) can be taken to dilate the coronary vessels of supply. Another obvious long-term way to reduce demands is for the overweight patient to eat less, and reduce the load of extra body weight on his circulation. It is very frustrating, to say the least, that such an incapacitating and often lethal condition should be caused by the narrowing or blockage of only two or three inches of narrow piping about one-eighth of an inch wide. One obvious form of treatment in theory would be surgical replacement of the piping (many larger arteries than these in other parts of the body are commonly replaced already), or surgical removal of the obstruction inside it. It is very likely that surgeons will one day overcome the technical difficulties involved.

Heart Attack or *Coronary Thrombosis.* It should readily be understood from the above description that heart attacks will vary in their severity according to the amount of heart muscle deprived of blood; and this in turn will depend on where in the coronary artery the obstruction occurs. Most usually it is the left ventricular muscle which is cut off from supplies and dies, either in part or in all of its thickness. Since it is the left ventricle which does most of the work of pumping blood to the body, serious heart failure (P27) is to be expected. If too much muscle is killed, the heart will simply stop, and the patient will suddenly die. It is much more usual, however, for enough muscle to be left for survival, albeit with a greatly reduced cardiac efficiency. A heart attack is usually accompanied by severe pain, similar to the pain of angina but more severe, and unrelieved by rest or by the patient's usual drugs. Very occasionally the event occurs apparently without pain, or with so little that it is ignored. These so-called "silent" coronary attacks can make diagnosis extremely difficult. Since the doctor depends very considerably with heart attacks on an exact, spontaneous description of symptoms for his diagnosis, no description will be given here. There are many over-anxious people who will read these words and could be misled into an unspontaneous description of their own symptoms, and this could make the task of treating them such a problem that they could even be mis-diagnosed as a result. If you have the smallest worry that your chest pain is due to your heart, take your anxiety to your doctor without delay. He will almost certainly be able to reassure you; and if it happens to be your heart after all, you will have taken the first sensible step towards proper treatment. Dangerous as heart attacks are, they are by no means the death warrant that many lay people think, any more than cancer is. The treatment for a true heart attack is urgent and prolonged. Patients must be at complete rest and their pain relieved quickly. The area of heart muscle they have lost must be allowed to heal with a good, firm scar, and this can take three months of rest often in hospital.

Blood-pressure. The blood is normally under great pressure in the arterial system, since it is this which forces it into all the tissues of the body. It is therefore no more meaningful to say you have "blood-pressure" than to say you have a temperature. You would be very badly off without. Blood-pressure which is too high, however, can give rise to problems, though not always. It is another of those conditions like angina and cancer, which engender much anxiety among people even when they do not suffer from them. For this reason doctors are often unwilling to disclose a patient's blood-pressure and because of this they unjustifiably earn a reputation for unreasonable secrecy. They are themselves to blame for the general public anxiety as the following true story shows. Twenty years ago a lady in her fifties wished to accompany her husband to a post abroad which was to last four years. All arrangements had been made—the husband resigned his previous job, sold the house, etc.—when it was discovered at a routine medical examination that she had a high blood-pressure, and she was very solemnly advised by the rather elderly doctor not to go. There was great consternation and emotional upheaval, not least because of the inconvenience involved. Eventually she was allowed to go at her own risk. The husband's job lasted eight years instead of four, during which the lady was in no way inconvenienced by her blood-pressure; except that she worried interminably about it. On returning home to retire she began to think she had angina, and elaborate hospital investigation revealed that, as might be expected, her arteries were not as young as they used to be. She was undoubtedly suffering from mild angina, but not as badly as she thought. The opportunity then arose, in her late sixties, to go abroad yet again, and this she did, living a quite strenuous life, and one which she enjoyed. At the time of writing she has returned home, and, twenty years later, at the age of seventy three is running a home very actively, still with very little inconvenience from her blood-pressure. There is no doubt that it has been very high all this time, and it is also certain that she will die one day, although it may well not be of her blood-pressure. How much better it would have been for her not to have been told it was high twenty years ago and to have avoided all these years of anxiety. It is not being suggested here that high blood-pressure is a trivial condition, but that it is for doctors to worry about rather than patients! If you ever find out your own blood-pressure, never try to work out for yourself what the figures mean. It is much too complicated. Finally, it should be mentioned that high blood-pressure may occasionally be associated with, or "secondary to," certain kidney diseases (*nephritis*) including a strange condition known as *toxaemia of pregnancy*, which lasts only as long as the pregnancy, provided great care is taken. Most high blood-pressure is, however, "primary", and without any known association or cause.

Low Blood-pressure. Some people seem normally to have surprisingly low blood-pressure all the time. There is nothing whatever wrong with this; indeed it may even be beneficial. At least they are unlikely ever to suffer the effects of high blood-pressure. The sudden low blood-pressure of circulatory failure or shock (P27) is another matter and must be urgently treated.

Irregularities of the Heart-beat. How quickly or how slowly the heart beats is largely under the control of the cardiac centre in the brain and the level of certain hormones in the blood. The *regularity* of the beat, however, is controlled by the so-called pace-maker in the wall of the right atrium, and by the way impulses from the pace-maker travel through specialised conducting heart cells (the bundle of His and its branches) to the ventricles. When any part of this elaborate mechanism is upset, either by altering the biochemical or electrical conditions of these specialised tissues, or by killing some of them off by deprivation of blood supply in the course of a heart attack, disordered rhythm can result. Increase (*tachycardia*) or decrease (*bradycardia*) in rate is nearly always a normal response to exercise, or anxiety. Very occasional irregularity, such as the mis-timing of an occasional beat is also quite normal in some people, although many are alarmed by it. Persistent irregularity, however, is abnormal. Its true nature can usually be elucidated by making an electrical record of the heart-beat—an electro-cardiogram. The commonest causes

are varieties of coronary artery diseases or rheumatic heart disease.

Pericarditis. The heart beats inside a bag or sac. At every beat its outer surface slides against the lining of the sac, lubricated by a small amount of fluid. This is the pericardial sac, the *pericardium* being strictly the lubricated membrane which lines the sac and which also covers the outer surface of the heart. Sometimes inflammation occurs—*pericarditis*—and the sliding surfaces become roughened and even separated by a fluid effusion. Very occasionally, so much fluid accumulates that the heart's action is seriously impeded. Pericarditis may be due to infection or to rheumatic fever, and it usually overlies the area of damaged muscle after a heart attack. This illustrates something which people rarely appreciate—that inflammation is not by any means always due to infection by bacteria. The last two varieties of pericarditis are quite free from germs (sterile).

Myocarditis. A term loosely applied to disorders affecting the heart muscle. There are lots of very rare causes. The really common ones are due to acute or chronic rheumatic causes or to coronary artery disease, both of which are described above.

Endocarditis or inflammation of the lining of the heart is a term loosely applied to any disorder of the valves or heart lining. All varieties of rheumatic valvular disease (P28) are included. Bacterial endocarditis in its several forms usually involves valves already damaged by rheumatic disease. It is a complication which is still much to be feared, though somewhat less so now that antibiotic drugs are available.

Atheroma or Atherosclerosis. This is the condition referred to above in which lumps arise on the lining of arterial blood-vessels. Although it is therefore a disease of the arteries, its importance lies in the way blood flow is held up, either by the lumps themselves, or by thrombosis ultimately blocking the narrowed portion of the pipework. The effects on the body are therefore those of depriving the tissues of blood. It is an astonishing fact that in England and America, more people die of the consequences of atheroma than of any other single disease, including all forms of cancer put together. Furthermore, cancer is mainly a disease of old age, whereas many of the effects of atheroma on men occur in early middle age. If narrowing of the artery is going to do significant harm it is easy to see that it will be of more consequence in those parts of the body where small-bore vessels are supplying tissues whose functions are necessary for life. Exactly such a situation exists in the heart and in the brain. An additional factor is that the arrangement of the blood supply in these tissues is such that any particular area has only one vessel leading to it. This is unusual among the tissues generally, where several alternative, or " collateral " vessels usually supply an area, and where others can take over if one becomes obstructed. We have, therefore, a situation in which perhaps the most important tissues —the heart and the brain—run the greatest risk of deprivation, and this leads to angina and coronary thrombosis on the one hand, and cerebral thrombosis and hæmorrhage (" stroke illness ") on the other, accounting jointly for about one death in every five. In addition, the effects of atheromatous narrowing are often felt in the legs, where the blood supply to the muscles is inadequate for exercise, leading to intermittent pain comparable with that in the heart in similar circumstances. This is called *intermittent claudication*, or intermittent closing of the leg arteries. In its most severe forms, it leads to the need for amputation, although in most cases early treatment can avoid this. It is small wonder that there is intensive research into the causes of atheroma, as with cancer, but it is probably true to say that we still know rather more about cancer.

A lot of attention has been given to the amounts o certain fats in the circulating blood, particularly cholesterol. This fat is found in larger amount in the blood of sufferers from atheroma, and i also found in the arterial lumps themselves Efforts have therefore been made to reduce bloo cholesterol by modifications of the diet, but it ha been extremely difficult to prove that this ha done any good. Many other factors are known t contribute to atheroma, and hence to hear attacks and strokes, some of which can be reduce and others not. Such factors are age, obesity high blood-pressure, and smoking cigarettes People who lead an active life, like bus conduc tors, seem to have less trouble than others wh are less active, like bus drivers. Sudden sever exercise, however, is bad if you are not used to it It is better, and life saving, to take regular, moder ate exercise. Women have less atheroma tha men, until the menopause when they begin t catch up, so that hormones have something to d with it. Serious starvation, such as occurred i the German-occupied territories of Holland an Scandinavia and in the concentration camp conferred one benefit—a freedom from atheroma but obviously we cannot all starve, and the puzzl remains. Like many of the more important out standing medical puzzles, there is no single facto responsible, and this is what makes it difficult t solve.

Aortic Disease. The aorta, the main artery o the body, running from the left ventricle dow through the chest and abdomen, also suffers fro atheroma, but is too wide (about an inch across to become obstructed. However, weaknesse occur in the thickness of its wall, sometimes du to syphilis but nowadays much more usually du to atheroma, which results in a ballooning out o a part of the vessel, rather like you sometimes se in an old bicycle inner tube. In days gone b these *aneurysms*, as the dilations are called reached an enormous size, and would wear awa the breastbone and ribs, to appear as large pulsat ing masses on the chest. Now that advance syphilis is less common, atheromatous aneurysm with a predilection for the abdominal aorta, i the one most commonly seen; and these days it i treated by replacement of the diseased portion o vessel. *Dissecting aneurysms* of the aorta ar another variety in which the blood, under hig pressure, somehow finds its way in between th layers of the aortic wall and then suddenly rips u and down the whole length of the vessel, separatin (or dissecting) one layer from another in its path Sometimes it tracks back towards the heart an suddenly fills the pericardium with blood t stop the heart's action altogether.

Embolism. This term refers to any foreign objec travelling in the circulation and becoming im pacted when it reaches a vessel too small for it t pass through. It may be a thrombus (P31), collection of cancer cells, a group of bacteria, chunk of infected pus from an abcess, a collectio of fat droplets or even a bubble of air. If it origi nates in a vein it travels to the right heart and t the lungs. If it comes from the left heart or a artery, it will impact in any part of the arteria tree. Reasonably enough an arterial embolu will commonly end up in those parts of the bod with the richest blood supply, like the brain, th kidneys, the liver or the bone marrow. A thrombotic embolus will cause death of the tissu in the area previously supplied by the blocke vessel, a condition known as *infarction*. Perhap the commonest source of thrombotic embolism f the lining of the heart chambers where a thrombu has occurred at the site of muscle damaged by heart attack. Massive pulmonary (lung) embol ism is usually the result of thrombosis of the le veins in people kept immobile following surger or childbirth. That is why postoperative patient are got out of bed for a while as soon as the firs day after the operation. The cells of a cance embolus usually die; but if they survive, a new cancer deposit begins to grow where the embolu impacts, and this is one of the ways cancer ma spread. An infected embolus may infect th vessel wall when it impacts, producing a weaknes

which may give way. Air embolism, if enough insoluble gas enters the circulation, can kill by making so much froth in the heart chambers as to impede the normal pumping action. If bubbles pass the lungs and enter the brain, all sorts of neurological disorders like scores of tiny strokes arise. The same sort of thing happens all over the body in the "*bends*" or "*caisson*" *disease*, in which the blood literally boils. It is due to a too rapid return to normal pressure from regions of high pressure at great depths or from pressurised chambers. Fat embolism sometimes occurs after fractures due to marrow fat entering damaged veins and being carried away to the lungs.

Thrombosis. This is not quite the same as clotting. It is the mass which arises when platelets adhere to the lining of blood-vessels or heart chambers. Blood clot accumulates among layers of deposited platelets and the thrombus therefore has structure, unlike pure blood clot. Thrombosis usually occurs when the lining of the vessel or chamber is damaged by atheroma or inflammation, or when the circulation becomes very stagnant. One danger is that it will become dislodged and travel as an embolus during the first week or ten days of its existence. After this time it is usually firmly incorporated into the vessel walls by cells which migrate into it from the surrounding tissue. The other danger is, of course, that the tissue previously supplied by the blocked vessel will die before a collateral circulation can be established. As previously explained, this is called infarction. All the technical terms in this section are used elsewhere and can be looked up.

Buerger's Disease or *thromboangiitis obliterans.* This is an inflammation of the arterial wall which leads to blockage by thrombosis. The leg arteries of comparatively young men are most commonly affected, leading to amputation in some cases. Unlike lung cancer, coronary heart disease, and bronchitis, which are known to be associated with smoking, Buerger's disease is only thought to be. There is a horrible tale of a young man who had lost all his four limbs after another, sitting on the hospital steps begging passers-by to light his cigarette for him.

Reynaud's Disease. This is a strange condition in which the finger tips and in severe cases all the fingers or the whole hand respond in an exaggerated way to cold. The vessels supplying the hand are constricted and the fingers go white as the blood drains from them. Then the capillaries dilate and become distended and filled with blood. But owing to stagnation it is venous and blue, and the fingers are therefore blue. Now we have all experienced this in very cold weather, but sufferers from Reynaud's disease, nearly always women, respond even to very slight cold, like putting their hands into cold water. Even emotional stress will start the process off. In very severe cases the fingers will be so deprived of blood for so long, that sores will develop and fingers can even be lost, but this is very rare, and can be avoided by an operation to cut the nerves which supply the circular muscle of the vessels concerned. In most cases it is sufficient to avoid getting the hands cold.

Frostbite. Strictly speaking, this is literally a freezing of the tissues. Although their freezing point might be expected to be close to that of water, it usually only occurs at temperatures below −13° C (8° F). The patient may feel a pricking feeling at first, and feel an area of firmer, pale skin on the cheeks, nose, ears, fingers, or toes. If these parts are numb with cold, the onset of frostbite may not be felt, and will often only be noticed by others. In countries where extreme cold is prevalent, it is usual for complete strangers to stop each other in the street and point it out when they see it. It is important not to rub the affected part, but contrary to popular belief it must be warmed as *rapidly* as possible. Fingers should be immersed in water as hot as the normal hand can bear (110° F). Many First Aid books still quite wrongly teach that return to warmth must be gradual.

DISEASES OF THE RESPIRATORY SYSTEM

INTRODUCTION.

When air is drawn in during the process of breathing, it is brought into very close contact with the blood passing through the lungs. In this way the air we breathe in, which contains 20 per cent oxygen, is confronted with "spent" blood returning from the tissues which contains much less, and oxygen therefore diffuses into the blood from the air. At the same time, the waste gas, carbon dioxide, passes by diffusion in the reverse direction from the blood into the air, because there is much more carbon dioxide in the returning "spent" blood than the tiny amount in the air we breathe. The blood is therefore continually circulating through the lungs and exchanging carbon dioxide for oxygen from the air we breathe in. When we breathe out, we disperse the carbon dioxide into the atmosphere.

When the air enters the nose or mouth, it passes into the windpipe or *trachea*, through the vocal cords in the pharynx. The trachea is held open all the time by rings of cartillage and is lined by a mucus-secreting membrane covered by millions of tiny "hairs" or cilia. These continuously waft a sheet of sticky mucus upwards, which traps any dust or other small particles we may have inhaled, until a collection of this material in the pharynx stimulates us to cough and expel the phlegm, usually to be swallowed. At its lower end, the trachea or windpipe divides into two, the right and left main *bronchus*. Each main bronchial tube enters a lung, one on each side, and proceeds to divide repeatedly within the lung until the air is being carried by more and more smaller and ever smaller tubes called *bronchioles*. There are many millions of these on each side, and each one ends in a collection of very small balloon-like structures —the air sacs or *alveoli*. If you were to cut across a lung and examine the cut surface in a good light, you would see that it is a spongy tissue, with many millions of tiny holes, each one just visible to the naked eye. These are the air sacs. In their walls run the blood capillaries, each one of which is a branch of the vessels carrying "spent" blood from the right side of the heart. At this stage, the blood is only separated from the air in the sacs by the walls of the capillaries and of the sacs themselves. Both structures are extremely thin, making for easy diffusion of the gases between blood and air.

The action of breathing is accomplished by two muscular mechanisms. One is by the muscles which move the ribs, and the other by the diaphragm, a sheet of muscle which runs across the body, separating the chest cavity from the abdominal cavity. These muscles are all actuated by nerves, just as all other muscles are. Those running to the muscles of breathing are organised by a mechanism in the brain known as the *respiratory centre*. It is this centre—one of the so-called vital centres of the brain—which receives information from many different sources, and translates it into instructions for the breathing mechanism. Thus, when you run for a bus, you will automatically breathe more deeply and more quickly because the respiratory centre has been informed about all the extra carbon dioxide in your blood which has been produced by the exercising leg muscles. Even the conscious instructions involved when you blow a trumpet, inflate a balloon, or during speaking, all pass first to the respiratory centre. It is the death of the cells of this and other vital centres of the brain that is the ultimate cause of death in everyone who dies.

Bronchitis may be acute or chronic. It is an inflammation of the lining mucous membrane of the larger air passages or bronchi, and results in much more secretion than the amount normally produced, mixed with some pus. The acute form is often caused by viruses, with "secondary" infection from bacteria. It may sometimes be caused by irritant gases, like the sulphur dioxide in smog. The chronic, or long-standing form of bronchitis is often associated with *emphysema*, in which the small air sacs of the lung architecture

are destroyed or distorted, leaving larger spaces than normal, often surrounded by fibrous scar tissue. Such an arrangement makes the normal gaseous exchange difficult between air and blood. While the exact cause of chronic bronchitis is difficult to discover, because it is such a mixture of causes, it is mainly associated with older age groups, particularly men, in damp foggy climates like ours in Britain, with polluted town air and especially with smoking. Smoking also makes any existing bronchitis much worse. Patients cough, and produce varying amounts of sputum, or phlegm. They often wheeze like asthmatics. This may go on for many years before the right side of the heart begins to fail (P27). Gradually, during this time, the chest tends to become barrel-shaped. Treatment consists of getting the patient to stop smoking or otherwise contaminating his lungs, preventing infection, particularly during winter months, with germ-killing antibiotics, and breathing exercises. The outlook for chronic bronchitis and emphysema is nevertheless not good, although many patients continue with their disease for many years, provided they take constant care to obey instructions and stop smoking.

Bronchial Asthma (not to be confused with *cardiac asthma*) is a condition in which the finer air passages become constricted due to an allergic response. In addition, an increased secretion tends to obstruct them and the patient wheezes. In many cases it can be shown that he is allergic to a particular compound in dust, or, less commonly, a foodstuff. This is the same sort of thing as occurs in the upper respiratory passages in hay fever, but the effect is on a different, lower part of the respiratory system. Many other cases are due to respiratory infection of some sort, probably combined with an allergy to the bacteria causing it. A predisposition to asthma is often inherited. Once a patient has become asthmatic, his attacks will be triggered off by such additional things as emotional stress, changes in temperature (particularly sudden cold), irritating fumes or smoke, and physical exertion. These are secondary factors, and although much of the treatment is concerned with them, it is unlikely that any of them are a sole cause of the condition. Treatment is directed at the relief of the breathing difficulty and of the wheezing, as well as the control of the causative factors. Many useful drugs are available to dilate the contracted air passages and reduce the obstructing secretions. Asthma in children often gets better as the patient grows up. Asthma is another condition made much worse by smoking. Patients should avoid extremes of cold and humidity, particularly outdoor exertion in cold, damp weather. They should also avoid exposure to respiratory infection.

Bronchiectasis. In this condition the bronchial air passages are abnormally and permanently dilated, and the normal structure of the walls destroyed. It is thought to be caused by obstructions of the tubes which lead to dilatation of the parts beyond. Secretions accumulate, and since they cannot easily drain away, they become infected. The infection helps to complete the process of destruction of structures in the bronchial wall. The patient has a chronic cough which often produces large quantities of purulent sputum, and there are often recurrent episodes of pneumonia. Diagnosis is made by a special X-ray examination—a bronchogram—in which a material, opaque to X-rays, is dropped into the air passages. This shows up the dilated and distorted tubes. In some cases, where the disease is localised to one part of the lung, it is often a good idea to cut out that portion, and this is particularly true in young people. Vigorous physiotheraphy, involving drainage of the lungs by placing the patient in a suitable posture, together with antibiotic drugs for the infection, are other forms of treatment.

Cystic Fibrosis is an inborn disease which affects chiefly the lungs and the digestive system. It is sometimes called *Fibrocystic disease of the Pancreas*, and sometimes "Mucoviscidosis." Until it was medically recognised twenty-five years ago, children affected usually died from pneumonia in the first year of life. This, of course, was before antibiotics were available for the treatment of infections. Today, cystic fibrosis is known to be the commonest genetically determined disorder affecting children in Britain. One child in 2,000 receives one of the abnormal genes from each parent. Such a child therefore has a double dose of the harmful gene, and will have the disease from birth. One person in 25 of the general population carries only one of these abnormal genes, and such an individual will not have the disease, but will be a carrier of the abnormal gene. If such seemingly normal carrier marries another carrier there is a one in four chance of each of their children being affected. The children, therefore, who actually develop cystic fibrosis, have inherited the disease *equally* from both parents, who are carriers, but are themselves unaffected by the disease. Although much has been learned about cystic fibrosis in the past twenty-five years, there remain many unsolved problems, and we still cannot define precisely the biochemical fault which causes it. The prospects for survival into reasonably healthy adult life are steadily improving, but they depend upon early diagnosis and careful management through childhood. In cystic fibrosis most of the damage is caused by the excessive viscidity, or stickiness, of the mucus which is produced in the breathing tubes as a lubricant, and also in the ducts of the pancreatic gland which provides enzymes to help digestion. Being thick and sticky, instead of thin and slimy as in the normal, this mucus tends to block the passages instead of keeping them clear. The pancreatic cells are permanently destroyed. The gland cannot secrete pancreatic enzymes, and the food, especially protein and fat, is not properly absorbed. This deficiency can be compensated fairly well by giving pancreatic extract by mouth with every meal, and by dietary care.

The major clinical problem is in the lungs. The lung passages normally have a thin coating of mucus which is propelled steadily upwards, and completely renewed in less than one hour. It moves more suddenly on coughing. In cystic fibrosis this upward movement is slowed down and interrupted. There is difficulty in keeping the passages clear, especially when infection with bacteria or viruses greatly increases the amount of mucus. This results in intermittent blocking of the air passages, difficulty in breathing, incomplete use of the lungs, and persistent local pockets of infection. If such infectious processes are not controlled, areas of lung will be destroyed, chronic infection will persist, and multiple lung cavities will develop. These predispose to further infection, interfering with the natural development of the lung—a process not normally complete until halfway through childhood—thus adding to the respiratory problems which the child will face in later life. Unless a correct diagnosis is made and proper treatment instituted before the first serious lung infection has occurred, the resulting lung damage may well be permanent. The Cystic Fibrosis Research Foundation Trust of Stuart House, 1 Tudor Street, London, E.C.4., was founded in 1964 to raise funds to finance research and to help and advise parents with everyday problems in caring for these children.

Pneumonia. This is an infection of the lung tissue, rather than of the air passages. The lung is the only internal organ which is directly exposed to the air, and since there are germs of all kinds in the air, it is a source of surprise that pneumonia is not a much more common event in all of us. The answer lies, as with all infections, in the fact that it is not simply (or even mainly) bacteria which cause disease, but our own lack of resistance to them. If we allow germs to thrive and multiply by being unhealthy or run down or undernourished, infective disease will occur. If we are fit, the entry of those same harmful germs into the body causes us no inconvenience, unless we are very young, or very old, or unless the invasion of germs is abnormally overwhelming. This helps to explain why pneumonia is so often quoted as the cause of death. In most cases it is merely the terminal event occurring in the elderly or those whose normal resistance is so far reduced by the

illness that they succomb to an invasion which they would normally not notice. There are two main kinds of pneumonia, and in both the air sacs become filled with inflammatory secretions, making the normally porous lung tissue as solid as liver. In *lobar pneumonia*, a whole segment (or lobe) of the lung becomes solid. In *broncho-pneumonia*, areas of lung tissue surrounding the smaller bronchioles become consolidated, leaving normal porous lung tissue in between. Broncho-pneumonia is the one which occurs in the rather stagnant lungs of people who are already ill or bedridden. Both forms respond to treatment with the appropriate antibiotics, provided any underlying debility does not interfere with the patient's own resistance. In the terminal bronchopneumonia of fatal illness, it is sometimes considered kinder not to treat the additional pneumonia. *Pleurisy* is a natural complication, and before the days of antibiotic drugs *lung abscess* was very much feared. Another form of pneumonia—*virus pneumonia*—has been referred to on P10(2).

Pneumoconiosis. This is a term which refers to a large group of different diseases, all of which are caused by breathing in some form of dust over a very long period of time. It is therefore an occupational hazard of certain trades. We have already mentioned the mechanisms of mucus secretion in the air passages which normally trap small particles from the air, and prevent them reaching the lung. However, in some occupations there is so much dust breathed in over the months and years that these normal barriers are defeated. About a quarter of the earth's crust consists of silicon, in quartz, flint, or sand. *Silicosis* occurs in people who have worked for many years in trades like mining, stone crushing, sandblasting, or metal grinding, who are often breathing silicon dust in high concentration. When the particles arrive in the air sacs, they set up an irritant chemical reaction which produces nodules of scar tissue. Silicosis for some reason predisposes to tuberculosis (**P14(1)**). Emphysema also occurs and there is a general impairment of respiratory function. Coalminer's pneumoconiosis is similar to silicosis but not identical with it. It is more prevalent in some coalfields than others, owing to the different composition of the dust to which these unfortunate men are daily exposed. It is hoped that modern mining methods will help to reduce this dread disease. Asbestos is a complex silicate of magnesium, calcium, and iron. *Asbes-tosis* is caused by inhaling its fine fibres. *Beryl-liosis* is caused by compounds of beryllium, used in the manufacture of fluorescent lamps. *Farmers lung* is a pneumoconiosis caused by inhaling hay and grain dust, and is similar to *bagassosis* and *byssinosis* caused by sugar cane and cotton dust respectively. The newest pneumoconiosis to be reported is *mushroom worker's lung*, caused by something in the compost in which mushrooms are commercially grown.

Pulmonary Embolism. This catastrophic, yet quite common condition has already been briefly referred to (**P30(2)**). It is a cause of tragic, sudden death in people who have had operations or have given birth to babies some days previously, or who have been bedridden for any other cause. The first event is that the blood in the veins of the legs becomes stagnant, due to the lack of exercise; and together with the tendency to clot which often follows surgery or childbirth, the whole length of a leg vein may be obstructed for twelve inches or more by an elongated clot of blood. This does little harm to the circulation of the leg, since there are plenty of other veins for returning blood to the heart. The danger is that the clot will become dislodged and be swept upwards towards the heart by the flow of returning blood. When this happens it is carried by way of the right auricle and ventricle into the pulmonary vessels which normally carry spent blood to the lungs. Here, for the first time, it enters vessels which are getting smaller as they divide, and it then impacts in the main pulmonary artery. The patient, who may have been recovering very well, suddenly collapses and not unusually dies there and then. At autopsy a long coiled-up mass of clot is found obstructing the pulmonary vessels. It often can be seen to form a cast of the leg vein and even bears the marks of the small venous valves which are present at its site of origin. With the dramatic advances being made in chest surgery, it is now sometimes possible in selected cases to operate to remove the clot. Success clearly depends on the patient's surviving long enough to be taken to the operating theatre for the major operation of *pulmonary embolectomy*. Three quarters of all cases of pulmonary embolism die within two hours, and therefore the best hope would be to prevent the occurrence altogether. This is not at present possible, but clotting in leg veins can be dis-couraged by early exercise following surgery and childbirth. Patients often resent having to get up the next day because it is so uncomfortable. Herein, however, lies their best hope of avoiding pulmonary embolism.

Haemoptysis. This means coughing up blood or blood-stained material. It must be distin-guished from *haematemesis*, in which the blood is vomited from the stomach. It must always be taken seriously because of the underlying lung disease which may be present. No one who coughs up blood, in however small a quantity, should neglect to inform their doctor so that its source can be determined. Hæmoptysis occurs in a variety of lung disease, some of which is not serious but much of which must be treated im-mediately if it is not to become so. This is a suitable place to repeat our general rule that you should see your doctor without delay if you have any unexplained bleeding from any part of the body, however well you feel. And this includes hæmoptysis.

Fat Embolism. Liquid fat sometimes enters the bloodstream following extensive crush injuries to soft tissue and bone. It splits up into millions of small globules which are carried to the lungs, and impact in small blood vessels there, producing obstruction of the lung circulation and consequent difficulties in breathing.

Lung Cancer. This is one of the nastiest and most incurable forms of cancer which can occur. It is also probably the easiest to prevent. There has been no reasonable doubt for several years now that it is associated with cigarette smoking, and the evidence is overwhelming. However, in spite of this certain knowledge, smoking continues to increase, and every year there are more and more people dying unpleasantly of lung cancer. It seems that nothing the health authorities can do is able to stop it. Intensive campaigns of public advertising of the dangers, and well organ-ised instruction in schools have so far made no impression whatever on the smoking habits even of people who accept the evidence. The only group of people who are known to have stopped smoking are British doctors, very many of whom have given it up, and it is easy to show that giving it up has saved them from the disease. Their colleagues who have not done so have continued to die. Undoubtedly a large factor contributing to the failure of anti-smoking propaganda is the enor-mous expenditure by the tobacco manufacturers on very clever advertising, amounting to many millions of pounds each year. Moreover they spend a pitiful fraction of this amount on their own research into the harmful effects of their own product, which has so far discovered nothing which was not already known by research doctors many years ago. Another problem is that it takes a number of years to get cancer. It is not like an infectious disease which is caught a few days after exposure to the bacteria concerned. It may be fifteen or twenty years before the cancer begins, and many smokers are apparently un-willing to look so far ahead. Furthermore, not everyone who smokes dies this way; and so a smoker can gamble with his life and hope it will not be him. The present writer once had to perform a series of post-mortem examinations on people who died of lung cancer, and this helped him to stop smoking completely, having smoked more than twenty cigarettes a day for several years. Not everyone can have this incentive. The main

encouragement to smoke probably comes from other people. Schoolboys are easily impressed when their teachers and parents stop smoking. They are not likely to fear the habit when these same people smoke openly. The smoking doctor is also a powerful stimulus to people to carry on smoking.

Lung cancer grows in the wall of a main bronchial air passage. If it grows inwards it can obstruct the air way, choking that part of the lung it is supplying with air. This causes collapse and infection of the lung and may lead to *lung abscess*. The patient will then cough up blood-stained infected and purulent material. Such a case is comparatively lucky, since the disease declares itself early by producing symptoms. In others, the lump may grow outwards into the surrounding lung and produce no symptoms at all in the early stages. Indeed, it may spread to other parts of the body, like brain or bone or liver before causing any trouble to the patient. If this happens he may go to his doctor because of fits, changes of personality, or fracture, only to discover that the origin of the trouble is in the lung.

The chances of cure are negligible, although much can be done to relieve the pain and suffering of the last stages of the illness. Not more than one in twenty cases is alive two years after it is first diagnosed. Surgery, by removing the lung, and irradiation of the growth are the standard palliative treatment. It is not the practice of the Medical Section to alarm the reader unnecessarily, but if only a few are induced to stop giving themselves such a horrible disease, then writing in this way will have been justified.

Secondary Cancer of the Lung. In nearly all forms of cancer, the big problem is that it spreads to other parts of the body. If this were not so it could be eradicated by surgical removal more often than it is. One common way in which it spreads from any part of the body is by entering the bloodstream and being carried as clumps of living cancer cells to distant parts. When these come to rest in smaller blood vessels, they begin to grow and colonise the new environment. Such new colonies are called *secondary deposits* or *metastases*. It so happens that all veins (except portal veins of the liver) lead to the right heart and thence directly to the lungs, and for this reason the lungs are a very common site of *secondary* cancer, which may have begun in the bowel, or breast, or indeed anywhere else in the body. Other common sites of secondary, blood-borne cancer are the brain, liver, bone marrow, and kidney, since all of them have an abundant blood supply, and there is therefore a high chance of the travelling cells arriving there. Secondary cancer of the lung usually consists of several lumps scattered throughout the lung. Lung cancer itself is usually only one growth. One of the main reasons for the success of early diagnosis is that treatment may be possible before blood-borne and other means of spread have occurred. Unfortunately, in the case of primary cancer of the lung, even early diagnosis is of little avail, but in many other common cancers permanent cure is possible if treatment is begun early enough.

Pleurisy. The chest is lined by one layer of a thin membrane called the *pleura*. The lungs are covered and enclosed by a second, continuous layer of this same membrane. When the lungs move during respiration, the pleura covering the lungs rubs against the pleura lining the chest, lubricated by a very thin layer of pleural fluid separating the two pleura. Whenever the pleural surface becomes inflamed, this is known as *pleurisy*. It is nearly always due to inflammatory disease of the adjoining lung, and is therefore not strictly a disease in its own right. For example, pneumonia, tuberculosis, lung cancer, or a lung infarct (P30(2)) will produce a pleurisy if the area of diseased lung adjoins the lung surface. Sometimes the area of inflamed inner pleura will tend to stick to its outer layer or rub painfully against it, producing a sharp pain when the patient breathes. Sometimes a large effusion of fluid is produced which separates the two layers and collapses the lung by occupying space in the chest which the lung should be occupying. This latter is more usual in tuberculosis or cancer.

The lung can be collapsed by the entry of anything between the normally adjacent layers of pleura. For example, air can be introduced, either deliberately to rest the lung in tuberculosis, or by accidental penetrating wounds of the chest wall, or by accidental rupture of the emphysematous lung (*q.v.*). This condition is called *pneumothorax* or "air in the chest." Bleeding into the cavity between the pleura is called *haemothorax*.

DISEASES OF THE DIGESTIVE TRACT AND LARGE INTESTINE.

INTRODUCTION.

The digestive tract consists of the mouth, pharynx, oesophagus (or gullet), stomach, small intestine, large intestine (or colon), rectum, and anus. The small intestine is very long, and is subdivided into the duodenum, jejunum, and ileum. It ends at the junction of the ileum with the cæcum, where there is a small blind side-tube, the appendix. The cæcum leads into the colon. The whole tract has two main mechanical functions and two main biochemical ones. Mechanically, food has to be chewed in the mouth and further minced up by muscular squeezing, mainly by the stomach. It has also to be propelled along by an orderly series of squeezing movements known as *peristalsis*. While it is still in the digestive tract, food has to be digested. That is to say, it has to be broken down chemically into suitable materials for absorption into the system, and secondly, it has to be absorbed across the wall of the intestine into the blood stream, itself a highly complex biochemical process. The blood stream it now enters is a special part of the circulation, the "portal" system, which travels directly to the liver without first passing to the heart. In the liver the broken-down foods are processed and issued in their new form into the general, or "systemic" circulation, by which they are finally carried to all the tissues of the body.

As the food passes along the digestive tract (or, as it is sometimes called, the alimentary canal), it is mixed with various secretions which are either made in the wall of the tract, or by organs outside the wall connected to the main pathway by small tubes. Examples of the latter are bile, manufactured by the liver and sent into the duodenum through the bile ducts. Also pancreatic juice comes from the pancreas down the pancreatic ducts, also into the duodenum. These secretions are either digestive juices concerned with splitting up the foodstuffs so that they can be absorbed, or they have a lubricant function so that the gut contents slide along easily under the influence of peristalsis. Roughly speaking, it may be said that digestive juices give place to lubricant secretions at the junction between the small and large intestine.

The constituents of the diet are dealt with in a later section. The principle classes with whose digestion we are now concerned are carbohydrates, proteins, and fats.

Carbohydrates are sugars and starches. There are many sugars, which may exist alone, in pairs, or with lots of them stuck together. Alone they are such things as glucose or fructose. Common table sugar is a substance called sucrose, formed by sticking one glucose molecule to one fructose molecule. Starch is lots of glucose molecules all stuck together. Digestion of carbohydrates consists of splitting up sugars and starch into single sugars like glucose, since only single sugars can be absorbed into the system. The splitting is done by digestive *enzymes* which are found in the juices secreted into the digestive tract. Sugar-splitters are found in the saliva of the mouth, in the pancreatic juice of the duodenum, and in the duodenum's own juice from its own wall. On the face of it, you might think it would be better to eat glucose which needs no digestion and can be absorbed in

this form, than to eat starch which has first to be split; and so a lot of money has been made out of a gullible public by the sale of glucose drinks and powder. In fact digesting starch is no problem whatever, even for the sick, who can obtain their carbohydrate energy just as easily (and much more cheaply) from potatoes as from expensive glucose. The end result of eating both is the same. The starch-splitting enzyme in saliva is mixed with the food as it is chewed, and it is therefore probably a good idea to chew it well. However, even if the food is bolted it does not seem to matter very much. People without teeth (neither their own nor dentures) seem to digest their carbohydrate quite well, presumably by means of their pancreatic juice at a later stage.

Proteins, which are found in meat, cheese, and eggs, have very large molecules consisting of lots of small ones strung together. Unlike starch, in which all the component glucose molecules are identical, the amino acids of which proteins are composed come in many different types. They all contain nitrogen, and there are about twenty-seven varieties. One protein differs from another in the proportions of the mixture and the order in which they are stuck together. Only single amino acids can be absorbed from the food, and so protein digestion again consists of splitting the material down into its building bricks. There is a strong protein splitting enzyme in the gastric (or stomach) juice called pepsin, whose job it is to split the long amino-acid chains into shorter chains. Several other protein-splitters in the duodenal and pancreatic juice contrive to break the smaller chains into individual amino acids which are then absorbed and sent to the liver for processing.

Fats mainly consist of glycerol to which are attached three fatty acid molecules for each molecule of glycerol. An enzyme in pancreatic juice splits the fatty acids off the glycerol, but would have some difficulty penetrating the globules of fat without the help of bile. One of the constituents of bile (bile salts) has detergent properties like washing-up powder and breaks the fat globules up into a very fine suspension so that the enzyme can get at the fat. Some fat particles of this size can even be absorbed as such, without preliminary splitting.

The processes by which all these enzymic secretions are produced are very finely controlled. They are very expensive to make in terms of energy and raw materials, and so it would be very wasteful to produce them all the time, even when there was no food to digest. And so the body has some very well designed automatic arrangements for sampling the foods as they are eaten and passed on, which ensure that exactly the right kind of juice is waiting in every part of the digestive tract for whatever food arrives. As soon as the food is digested the supply of enzymes is automatically switched off, so that there is very little waste of precious materials. It is, of course, beyond the scope of this account to describe the control mechanisms. Suffice it to say that they are operated partly by nerve reflexes which signal the imminent arrival of food, and partly by special hormones produced in various parts of the gut wall. The best secretion is affected even by psychological factors, so that pleasant company and surroundings, attractive appearance of the food, and an eager anticipation of it all make for good digestion and good health. These psychological factors are all capable of proper scientific investigation and proof. The poor health of those who habitually and irregularly bolt unpalatable food is probably due to such factors as these. So is the failure of appetite in the depressed, the anxious adult, or the scolded child.

Nearly all the digestion which has been described occurs in the stomach and upper part of the small intestine (the duodenum, jejunum, and upper ileum). Almost all absorption of the products of digestion occurs in the small intestine which is long and intricately folded to give it a large surface area for this purpose. The colon, or large intestine, is adapted for conserving water, by removing it from the residual waste material. This has then to be eliminated, and being rather dry its passage has to be lubricated by suitable secretions of mucus.

Constipation. Here, perhaps we had better mention the morbid question of constipation, about which so many people are obsessed and hold such pronounced views. First of all, what is it? For some people it is entirely normal only to pass motions about once or twice a week. For others the normal frequency is once or twice a day. What is abnormal? The answer is that the only thing worth worrying about is any pronounced change of bowel habit, particularly in middle-aged and older people. By a change is meant a change from that individual person's normal routine. Such a pronounced change—either in the direction of constipation or diarrhœa is worth consulting your doctor about if it persists for more than a week or two. Otherwise, forget your bowels and leave them to work naturally as they know best. Many believe that constipation is the root of all evil, that it causes a mysterious condition known to them (although, alas, not to doctors) as "autointoxication." Assiduously fostered by the manufacturers of patent medicines, their beliefs range from the notion that headaches, spotty skin, muddy skin, and tiredness are caused by constipation, to the more extreme idea that the whole system is being poisoned and that, if the bowels do not work, the individual will shortly die. Of course, all this is the merest rubbish; for, as Professor Samson Wright, whose *Applied Physiology* is one of the most famous of medical text-books, has pointed out, there is no such thing as absorption of poisonous products from the bowel. There is no such thing as "auto-intoxication." "The symptoms of constipation," he writes, "are largely due to distension and mechanical irritation of the rectum." It has been shown that an enema removes these symptoms *immediately*, which would not be the case if they were due to poisons in the blood, and exactly the same symptoms can be produced by packing the rectum with cotton-wool. Wright mentions the case of a man who went for just over a year without a bowel motion, and at the end of that time, although his abdomen was distended and he felt some discomfort, he was not noticeably ill. Needless to say, telling these facts to the purgative addict will only make him annoyed, but it is as well to note that if no known diseases are due to constipation (although constipation may be a symptom of another disease), the regular use of purgatives *can* cause disease.

Constipation should be treated first by diet containing plenty of roughage—bran and oatmeal are excellent—plenty of stewed and fresh fruits, and at least three pints of fluid should be taken daily. Failing that, one of the best things to take is a proprietary product prepared from senna pods. Never to be taken regularly are liquid paraffin, castor oil, preparations of aloes, Epsom salts, and all the other dreadful stuff that people swill down.

Œsophagus.

The œsophagus, or gullet, is more than a simple tube for taking the food from the mouth to the stomach. It is normally closed except when swallowing, and the act of swallowing is very complicated. When the material to be swallowed arrives in the back of the throat there is an automatic mechanism which opens the top end of the œsophagus to receive it, and from then onwards everything happens automatically. The next portion of the tube opens and the top closes strongly, so that the food (or drink) is propelled forcibly down the next segment. Then the part below this relaxes and the material is squeezed further downwards and so on until it arrives in the stomach. This squeezing (or milking) action is akin to the action known as peristalsis which propels contents in other parts of the gut. Thus when you see someone swallowing a glass of beer very quickly in warm weather, it is not going "down the hatch" under the influence of gravity, however much it may look like it. It is perfectly

possible to swallow the same, or any other liquid, standing on your head. Getting into that position is the only difficult part. Sometimes this complicated swallowing mechanism gets out of order, leading to difficulties of swallowing, or *dysphagia*. Another disorder known as *hiatus hernia* occurs at the lower end of the œsophagus as it meets the stomach. At this point the œsophagus has to pass through the diaphragm, the sheet of muscle which separates the chest from the abdomen. The muscular fibres of the diaphragm are normally arranged in a ring around the œsophagus. These help to keep the lower end shut, so that the acid contents of the stomach do not regurgitate upwards, causing inflammation (*œsophagitis*) or heartburn. A hiatus hernia is when muscle fibres get slack, and the upper end of the stomach can even slide upwards into the chest. People with hiatus hernia get heartburn after meals, and particularly when they bend down or lie down. Except for very severe forms, which need surgical repair, the treatment is to eat less at a time, reduce the acidity with a suitable antacid and reduce weight, so that the weight of the abdomen does not press upwards so much. The other disease of the œsophagus, quite unrelated to the above, is *cancer of the œsophagus*, the cause of which is still unknown in most cases. When cancer occurs in the wall of any tube, it will often encircle the tube and gradually narrow the way through. This is what happens in the œsophagus, leading to difficulty in swallowing, particularly solids. It is a condition, usually, of rather elderly men, although it is sometimes associated with a special form of severe anæmia in women. Treatment is in some way to keep the passage open, either by transplanting a new tube, or more usually, by removing the constricted piece and joining up the remainder.

The Stomach and Duodenum.

By far the commonest diseases of the stomach and duodenum are *gastric ulcer* and *duodenal ulcer*. They are actually the same condition in two different sites and are often classed together as *peptic ulcer* or *acid-peptic disease*. The ulcers, which are rather like sores on the lining of the stomach or duodenum, may be "acute" or "chronic." Acute ulcers tend to be small and there are often several of them. Chronic ulcers are usually single. They may be small, or they may be several centimetres across. Chronic ulcers smoulder for months and even years, like a sore which will not heal, and a great deal of scar tissue forms in their depths. Thus they may in time erode their way right through the wall of the stomach, destroying all its layers, and begin to eat into surrounding structures like the pancreas or liver. The fact that they do not perforate more frequently is due to all the fibrous scar tissue which is formed during the slow eroding process. Healing of such a destructive ulcer is nevertheless common, and the great problem is how to help the natural healing process to win against the ulcer's tendency to erode. Better still would be to discover the cause, and prevent it happening in the first place. This extremely common affliction is confined to the human species and has been known since the earliest times. It does not vary very much with diet or with social class. Although occurring at all ages, it usually begins between the ages of twenty and forty, and is most commonly found in men between forty-five and fifty-five. Gastric ulcer is four times, and duodenal ulcer ten times more common in men than in women. It is always due to an inability of the lining to stand up to the normal digestive activity of the stomach contents. These are normally acid and contain a powerful enzyme for digesting proteins. Again it is perhaps more surprising that we all do not digest our own stomachs, rather than that some unfortunate people do digest small areas slowly. In certain abnormal conditions when the stomach stops making acid, ulcers always heal. However, some ulcers occur without excessive secretion of acid and many heal without the acid being neutralised with antacids. All this points to the main trouble being in the response of the lining to acid, rather than to the acid itself. Nevertheless, the most effective treatment at present known involves regulating gastric secretion, and particularly its acidity. It is also known that peptic ulcers are more common in people whose occupations involve administrative and professional responsibility, competitive effort and nervous tension, long periods of anxiety or frustration. Presumably the higher nervous system influences these events by the same nerves, which normally help to control secretion.

The main symptom of peptic ulcer is pain, and this usually responds well to proper doses of antacids. Many different varieties are available and a lot of money is made from selling them. When indigestion persists for longer than a few days it is always better to see your doctor so that a proper diagnosis can be made and the best remedies begun. Many other causes exist for similar pains, and you should not try to make the diagnosis yourself. It may be necessary to analyse your gastric secretions in the hospital laboratory. Almost certainly you will have a special X-ray examination, and since the stomach cannot easily be seen on a normal X-ray, they will have to show it up by making you drink a white material containing barium. This will be seen as a silhouette of the stomach and duodenal contents. Searching for an ulcer this way is a highly skilled matter and is performed by doctors specially trained in radiology.

Treatment of peptic ulcer is designed to relieve symptoms, heal the ulcer, and prevent complications (see later). Some rest and sedation may help to deal with the psychological influences at work. A special diet may be required. If certain foods cause discomfort they will naturally be avoided, but there is no evidence that any particular foods, like coarse or highly seasoned things retard, or that a soft, bland diet enhances healing. The era of sloppy, milky diets is almost over, for which countless ulcer sufferers will be profoundly thankful. Suitable antacids will be prescribed. Once an ulcer is diagnosed, the time has come to stop treating yourself with antacids from the chemist's counter, and to take the ones your doctor decides are best. Smoking should be stopped by ulcer patients (as, indeed, by everyone else, but that is another matter) because it inhibits healing. Alcohol tends to increase acid secretion and should be avoided. It is also *extremely important* to avoid taking any form of aspirin, even in quite small amounts, since this can lead to very serious bleeding from the ulcer. The ulcer patient should be warned that hundreds of proprietary preparations contain aspirin and all of them are dangerous for him. Search for the formula in small print on the label before taking any remedy, looking particularly for acetyl salicylic acid—the correct name for aspirin. Doctors have been pressing for years for a law which would make it obligatory for patent medicine manufacturers to label aspirin-containing drugs clearly. There is still no such regulation, so that even some widely sold "hang-over" remedies which are sold for "upset-stomach" contain large quantities of aspirin. Some of the patients with "upset stomach" are, of course, ulcer patients, and some even die of haemorrhage following the ingestion of aspirin.

The main complication of peptic ulcer are bleeding, perforation, and a narrowing of the pylorus, or lower part, known as *pyloric stenosis*. Bleeding is caused by the eroding ulcer eating away at one of the many blood vessels in the stomach or duodenal wall. It leads to the passing of "altered" blood in the stool (*melaena*), or to the vomiting of blood (*haematemesis*). When the initial bleeding occurs, the patient may feel suddenly faint, and a little later will notice the black, tarry colour of his stool. This is sometimes confused with a similiar colour when the patient is taking iron. Peptic ulcer is not the only cause of this very serious hæmorrhage, which constitutes a hospital emergency whatever its cause. The treatment, like that of every large hæmorrhage, is blood transfusion which must be continued until the bleeding stops, or until the patient is sufficiently fit for surgery, should that be deemed necessary. Perforation is perhaps the most serious complication of peptic ulcer, leading to the spilling of stomach contents within the abdominal cavity. Treatment is invariably surgical, either

the closure of the perforation or the partial removal of the stomach.

Surgical removal of part of the stomach is often the only way to treat a peptic ulcer which has had its chance to heal in other ways. It is tempting for the patient to "have it out and done with", but the time for surgery is a matter of fine judgment. So many ulcers heal by medical means if you give them a chance, and operations are for those which persistently refuse, or which become complicated.

Stomach Cancer. The stomach is a fairly common site for primary cancer. There is no known reason for this, and it is particularly important to stress that we know of no connection whatever between the peptic ulcers which have just been discussed and cancer. Stomach cancer used to be the commonest cancer of men, but the current rise of lung cancer has pushed it into second place. There are some strange geographical differences in its distribution. For example, it is much commoner in Japan and Scandinavia than in England or the U.S.A. It is difficult to see any reason for this in dietary habits. In Wales it causes three times as many deaths as in South-East England. All this is very puzzling, as is so much of our information about cancer generally. One of the main problems with stomach cancer is that it often causes the patient no inconvenience and thus produces no symptoms of note until the disease is far advanced and it is difficult to do much. Treatment is by surgical removal of the growth, and even in the most advanced cases a great deal can often be done to make the patient more comfortable.

The Small Intestine.

The small intestine runs from the stomach to the cæcum and comprises the duodenum, jejunum, and ileum in that order. On a more cheerful note it may be remarked that it is very rarely the site of cancer. Its main problems arise in connection with defects in absorption mechanisms, with obstructions, and with a strange inflammatory condition known as *regional enteritis*. Most obstructions are due not to blockages of the tube, but to failures of peristaltic propulsion, the process which is briefly described above under "œsophagus." Such a failure is called *ileus*. When peristalsis stops for any reason, the result is severe dehydration and loss of important chemicals like sodium and chloride from the body. This is because about two gallons of fluid enter the small intestine each day in the form of digestive juices, and all of this has to be pushed onwards to be reabsorbed into the system at lower levels. If peristalsis fails, this bulk of fluid remains in the small intestine, or is vomited. In both cases it is lost to the body itself, leading to serious dehydration and illness. Treatment is by very careful replacement by transfusion of the fluid and the chemicals lost, and by removal of the trapped fluid within the intestine through a tube threaded down through the mouth.

Regional enteritis or *ileitis* is sometimes known as *Crohn's disease*. It is a very mysterious condition in which the normally supple wall of the small intestine becomes inflamed and gradually replaced by thick fibrous scar tissue, so that it looks and feels like a thick garden hose. Loops of inflamed gut stick together, and channels open between them, and if the disease progresses a mass of adherent, thickened intestine results to which everything in the neighbourhood also adheres. However, for some unknown reason some cases do not progress downhill in this way and get better spontaneously. Surgical treatment is necessary for the majority, however, particularly those with advanced disease leading to complications such as obstruction or perforation. Sometimes an early case can be resolved by cutting out the length of affected gut, although recurrences are unfortunately common.

Appendicitis. This must be one of the best known surgical diseases of the intestinal tract. The appendix is a narrow, blind-ended side tube attached to the cæcum near the end of the small intestine. Appendicitis is when it becomes obstructed, or infected, or both. From its position it is almost predictable that it will get obstructed sooner or later by pieces of fæcal matter which pass its entrance and which are normally infected. The surprising thing is that it does not happen more often. Once this has occurred, however, a closed abscess forms, and as the abscess distends the appendix, it first weakens its wall, making it gangrenous, and then bursts into the abdominal cavity causing *peritonitis* (see later). It would be useless and misleading to describe the symptoms of acute appendicitis in detail, since it is difficult even for experienced doctors to distinguish them from those of several other conditions. Suffice it to say that any severe, persisting pain in the abdomen, whether continuous or intermittent, whether associated with diarrhœa or not, should lead the sufferer to a doctor for a quick diagnosis. Germ-killing antibiotics are useless against appendicitis, and any laxative is extremely dangerous as it may cause an acutely inflamed appendix to perforate.

The Large Intestine or Colon.

The two main serious diseases of the colon are ulcerative colitis and cancer in its various forms. *Ulcerative colitis* is yet another mysterious disease in which severe ulceration of the lining of the colon gives rise most frequently to diarrhœa with the passage of blood and mucus. In fact it can be like dysentery, and it has often been considered to be due to some form of infection. Unfortunately no particular germ can routinely be found in these cases, and the situation is endlessly confused by the presence in the normal bowel of lots of different germs anyway. Nevertheless the ulcerated lining of the bowel certainly does get infected by the germs normally present, and this makes the disease worse. Therefore germ-killing antibiotics are often helpful in alleviating symptoms and can lead to an earlier settling down of the condition, although not to a cure. It has long been known that certain kinds of psychological upset are often associated, but here again the disease is so unpleasant for the sufferer that he is to be forgiven some despondency as a result of, rather than as a cause of, his troubles. It is also suspected that ulcerative colitis may be an auto-immune disease; that is it may represent rejection by the patient of his own colonic lining in a manner somewhat comparable to the tissue rejection which often follows organ transplantation. Some of the more alarming complications are perforation through the wall of the ulcerated bowel, and sometimes massive hæmorrhage occurs. Medical treatment takes the form of keeping the patient in good physical condition in spite of his fluid and blood loss and his frequent lack of appetite. Surgery is often required to relieve obstruction, deal with perforation, remove chronically affected parts of the bowel, etc.

Cancer of the Colon and Rectum. This is another very common form of cancer, which can often be completely cured by surgical removal of the growth provided it is caught in the early stages before it has spread. The commonest symptom is a change in bowel habit, either towards constipation or, more often, towards diarrhœa, in the second half of life. There may be rectal bleeding, or the passage of mucus, and there may be abdominal pain. We cannot too often repeat that any such change of bowel habit, or any unexplained bleeding from any site should lead the patient promptly to his doctor.

Diverticulitis. Some people have small pockets or sacs in the wall of the colon known as diverticula. A minority of these sometimes get inflamed, and this is *diverticulitis*. Occasionally perforation occurs.

Hernia or Rupture. This is a condition in which abdominal contents, usually a loop of intestine, protrude forwards through the muscular

wall of the abdomen. The wall consists of a sheet of muscle fibres running in several directions. They normally become tense when we cough, or strain, or in getting up from a recumbent position. There are places in the groin on each side where there is a way through the muscle for the spermatic cord in the male. In many men a weakness can arise at this point, and if it persists, the way through may enlarge and allow loops of bowel to emerge from behind the muscle sheet to appear as a lump under the skin of the groin. On relaxation the lump can be made to disappear by pushing the contents back the way they came; and they will re-emerge when the patient strains. This is an extremely common complaint in men, and it should be treated by an operation in which the muscle wall is repaired. Some men, however, neglect to have their rupture treated until one day it proceeds to "strangulate." This is the term used when the muscle tightens around the neck of the protruding loop of bowel, cutting off its blood supply. From then onwards the loop becomes gangrenous and the intestine is obstructed by having a part of itself nipped outside the abdominal wall. The patient is in severe pain, vomits continously, and quickly is liable to get into such a poor condition that surgical relief is difficult. It is therefore a surgical emergency, and it would have been better to have had the relatively simple repair operation earlier and at leisure. Hernia in the region of the groin is of two types: *inguinal hernia* and *femoral hernia*, the difference between them being technical and of no consequence to the patient. They nearly always occur in men. Other types of hernia less frequently occur in both sexes. *Incisional hernia* is when the muscle wall has been weakened at the site of an old abdominal operation and has failed to heal properly. *Umbilical hernia* occurs owing to the natural weakness of the abdominal wall at the navel, and is so common in babies as to be almost normal. When a baby cries and thereby puts a strain on his abdominal wall, a lump often appears in the region of the navel, and this can be very alarming for the parents. They should of course show it to their doctor who will nearly always be able to reassure them. It is self-healing without operation in the majority of cases.

Peritonitis. The cavity of the abdomen in which the intestines and other organs lie is called the peritoneal cavity, and it is lined by a thin membrane called the peritoneum. When this becomes inflamed the condition is a serious one and is called *peritonitis*. Inflammation may be bacterial, as occurs following a burst appendix and the spillage of bacteria and pus in the cavity. It may be a sterile peritonitis as often follows perforation of a peptic ulcer, when the inflammation is caused by the acid contents of the stomach. It is always very dangerous, probably because of the large surface area afforded by the peritoneum for the absorption of inflammatory toxins.

Hæmorrhoids are simply varicose veins in the rectal and anal regions. They are very common, and are caused probably in about equal degrees by inherited weakness of the veins, strain such as heavy lifting, and constipation (this is one of the very few conditions in which constipation may do some damage, due to the mechanical pressure of hardened fæces in the rectum on the veins). Pregnant women are liable to develop hæmorrhoids or "*piles*," as they are commonly called, owing to the pressure of the baby's head in the pelvis. Hæmorrhoids may be external or internal, the former being in the anal region below the sphincter, the latter in the rectum; the two usually go together. There may be no symptoms, but the veins are liable to bleed, to get thrombosed (*i.e.*, a clot forms within) or to become infected. When clotting or infection occurs the piles enlarge and tend to be pushed out through the anus during defæcation, when they form extremely painful external swellings. Treatment in simple cases may be by the use of suppositories—cones of a firm grease containing suitable medicaments which are inserted in the rectum—in other cases the veins may be injected, as with varicose veins of the leg, in order to close them, but when there is much bleeding, thrombosis, infection, or interference with bowel movements they should be removed surgically.

DISEASES OF THE LIVER AND GALL-BLADDER.

The functions and site of the liver have been described elsewhere, so no more need be said about these. Presumably the most common associations of the layman in relation to the liver would be the two words "liverish" and "jaundice." Feeling *liverish*, one gathers, produces a sort of sensation like a hangover (which it frequently is), but there is no medical term corresponding to the word, nor is there any reason at all to suppose that it has anything whatever to do with the liver. Most likely it is an attack of mild gastritis, and should be treated as such.

Jaundice is easily recognised by the yellowish skin, the degree of colouring depending upon the severity of the case. In mild cases it may only be noticeable in the whites of the eyes. Less well-known symptoms of jaundice are itching of the skin, dark-coloured urine and pale motions, depression, loss of appetite, and tiredness. Jaundice, however, is not in itself a disease; rather it is a symptom of many diseases, amongst which some of the commonest are:

(1) Blockage of the bile ducts, which normally carry the bile and its pigments into the intestines (it is the pigments which produce the yellow coloration). The blockage may be caused by gall-stones, parasites, tumours, or in the liver itself when cirrhosis is present. The bile pigments, unable to get through the duct into the intestine—hence the pale motions—pass backwards into the blood-stream and are filtered into the urine, which therefore becomes stained, and into the skin. This is known as *obstructive jaundice*.

(2) *Infective jaundice*, on the other hand, results from various types of organism such as spirochætes and viruses. Examples are infective hepatitis, spirochætal jaundice, yellow fever, malaria, and some cases of syphilis. Certain poisons, such as chloroform, arsenic, phosphorus, and snake venom, can also cause jaundice, which in this case is due to damage to the liver.

(3) *Haemolytic jaundice* is found is some blood diseases, such as pernicious anæmia, acholuric jaundice, and blackwater fever. Its immediate cause is breaking down of the red cells at a rate too rapid for the liver to absorb the products.

The treatment of jaundice depends entirely upon its cause. The infective and hæmolytic types have already been dealt with under infectious diseases and diseases of the blood respectively, so it only remains to deal with obstructive jaundice, and this leads us to the subject of the gall-bladder and *gall-stones*. Doctors in their perverse way refer to inflammation of the gall-bladder as *cholecystitis* and to the condition of having gall-stones as *cholelithiasis* (just as Americans refer to typists as "stenographers" and lifts as "elevators").

The gall-bladder is pear-shaped and lies below the liver. It ends, at the "stalk" of the pear, in a tube called the cystic duct, which enters the main bile duct passing from the liver into the beginning of the duodenum. Bile is essential to the digestion of fats, and when a meal is eaten a supply of dilute bile moves down the main duct from the liver, whilst more concentrated bile is squeezed into the same duct from the gall-bladder. The bile, both dilute and concentrated, then enters the duodenum to do its work. In cholecystitis, which may be acute or chronic, the walls of the gall-bladder become infected, usually by streptococci or the bacillus coli, and severe pain develops over the liver area, typically spreading back to the right shoulder-blade. If the infection becomes worse and pus is formed there may

be a high fever. Gall-stones may, as some physicians believe, be the aftermath of such an infection, although others think that they are formed because of some defect in the ability of the body to deal with fat and cholesterol. In any case, gall-stones are formed in the gall-bladder, and may number anything from one or two to several hundred; their size varies from that of a grain of corn to that of a golf ball. Stones may be present without causing any trouble at all, but usually sooner or later the following symptoms develop: indigestion after eating fatty foods, heartburn, nausea, and attacks of pain. The pain of gall-bladder disease, whether in the case of simple infection or gall-stones, is more or less the same—over the gall-bladder area and passing to the right shoulder-blade. Such pain signifies either infection, which, of course, may occur without stones, or else that a stone formerly lying quietly within the gall-bladder has passed into the bile duct and got stuck.

Typically, gall-bladder disease is found in men and women in middle age, but it is three times commoner in women. As an aid to examinations, students are told (or used to be told) that the typical case is a woman who is "fat, fair, forty, and fertile," for there can be little doubt that pregnancy plays some part in upsetting the secretion of bile in some people. But it is also entirely possible for thin men to develop the disease, so there is no general rule.

When the stone blocks the cystic duct (*i.e.*, the one leading from the gall-bladder to the main duct) there is pain, which may be relieved when the stone either moves back into the bladder or passes into the main duct. The next problem is whether it can negotiate the opening of the main duct into the intestine; for if this duct is blocked *none* of the bile can escape and, passing back into the blood-stream, it produces jaundice.

Operation is necessary when acute inflammation is present, when there are frequent attacks of severe colic and other symptoms causing discomfort, or when jaundice is present. Drugs can cause only temporary relief when a gall-bladder becomes troublesome. There is no such thing as a drug which dissolves gall-stones.

The liver may be the site of cancer, but this is nearly always secondary to cancer elsewhere. Primary cancer, that is cancer originating in the liver, is not common. So, too, the liver may become enlarged, sometimes very considerably so, as a result of events elsewhere in the body: heart failure, leukæmia and other blood diseases, and even rickets can cause enlargement. In the liver itself enlargement may be due to cancer, cirrhosis, abscesses, and cysts (the former usually caused by amœbic dysentery, the latter by parasitic worms; both of which are described elsewhere). Abscesses are usually aspirated—which means that a needle attached to a syringe is passed in and the pus drawn off—cysts have to be surgically removed.

Cirrhosis of the Liver is a condition in which more and more of the liver cells become replaced by fibrous tissue. Now, as we have seen, the whole portal system which carries away the end-products of digestion passes into the liver, so when the liver becomes fibrosed there is serious obstruction to the portal circulation, leading to back-pressure in the veins, and therefore the liquid part of the blood, the plasma, oozes out through the walls into the abdominal cavity. This is known as *ascites*, and it is also found in some cases of heart failure, kidney disease, and chronic peritonitis. Formerly the fluid was removed by tapping the abdominal cavity but modern drugs for increasing fluid loss by the urine are usually successful.

Cirrhosis is always a serious disease: for, although Nature is so generous as to give us 80 per cent. more liver than we need to preserve life, the common type of cirrhosis extends right through the liver, and the secondary effect of portal obstruction with ascites complicates the matter. The disease in the West is often associated with alcoholism, especially in those who drink large quantities of spirits (there are other types of cirrhosis which need not be mentioned here); but the problem is more complicated than might appear, for everyone who drinks to excess does not develop cirrhosis. In fact, cirrhosis is not at all common, and some seem more liable to it than others. It is believed that another unknown factor, possibly malnutrition, is involved and the disease is not due solely to alcohol as such.

Symptoms are: chronic gastritis, morning sickness, constipation. Later, when the portal system has been seriously obstructed, large veins are seen on the abdominal wall, especially around the umbilicus. These develop in an attempt to compensate for the blocked portal circulation. Ascites and slight jaundice are later symptoms. Treatment is a matter for the specialist, but obviously alcohol should be banned. Recently, an operation has been devised in which the portal vein, instead of going to the liver, is sutured to the *vena cava*—the largest vein in the body, which passes up the centre of the abdomen just in front of the backbone on its way to the heart. This operation is known as *porta-caval shunt*. Not infrequently the first sign of cirrhosis is serious hæmorrhage from the mouth due to the rupture of "varices" (*i.e.* varicose veins) at the end of the œsophagus.

The Pancreas.

This is a soft, elongated gland lying behind the stomach; it is about 5 in. long and 2 in. wide. Within its tissues lies the duct, which, when it leaves the pancreas, passes into the duodenum near the point of entry of the bile-duct. This duct transmits the juices containing enzymes which aid in the digestion in the small intestine. The pancreas, however, has two main functions: not only does it manufacture these important digestive juices, but in certain specialised areas, known as the islets of Langerhans, it manufactures insulin. The functions of insulin will be discussed shortly when we are dealing with diabetes.

Like the liver, the pancreas may be the site of cysts or tumours. The only other condition which need be mentioned is *acute pancreatitis*. This is a not very common disease which is caused by a small gall-stone becoming stuck in the opening of the duct. When this occurs, bacteria come in to infect the pancreas, and the blocking of the duct prevents the digestive juices from leaving, with the result that the organ is digested by its own enzymes. There are all the signs of an acute abdominal disturbance: sudden severe pain, vomiting, and fever. Pancreatitis is difficult, even for the expert, to diagnose, and formerly was always treated surgically, but today it is often possible to clear it up with medical treatment and the use of penicillin or other antibiotics.

Diabetes. Although we know so much about diabetes, we still have not the faintest notion as to what causes it. Its immediate cause is a failure in varying degrees of the pancreas to produce insulin, but examination of the pancreas rarely reveals any significant changes. The disease is commonest between thirty and sixty years, but may occur even in children. Now, insulin is the substance which makes it possible for the body to make use of sugar—the glucose which is the end-product of carbohydrate digestion. So in its absence the glucose, although there to be used, is useless to the body and accumulates in the blood, finally passing out in the urine. (The fundamental test for diabetes is the discovery of sugar in the urine by the use of certain simple procedures.) The diabetic, then, is being starved of sugar no matter how much he takes in, and the excess sugar in the blood which cannot be used acts as a poison, which, in extreme cases, sends the patient into coma and may—indeed, in former times, usually did—result in death. The symptoms of diabetes vary, of course, with its severity, but in the main they are: increasing appetite in an attempt on the part of the body to supply the sugar which is there but so tantalisingly unavailable, great thirst, because this useless sugar has to be excreted, and the production of urine demands water, frequency in passing urine, and increasing loss of weight in spite of all that is taken in. In severe and untreated cases boils, itching of the skin, gangrene of the limbs, and finally coma and death may occur.

Although mild cases of diabetes could, and still can, be treated by dieting alone, by reducing the intake of carbohydrate, the diagnosis of diabetes

prior to 1922 amounted almost to a death-warrant. In that year, however, the Canadian physicians Banting and Best separated out the secretion of the islets of Langerhans and named it "insulin"; they showed that insulin taken from the pancreas of animals and injected into the diabetic patient was just as effective as the home-made article.

Since a diabetic regime has to be decided on by the doctor according to the severity of the disease, no useful purpose would be served by discussing the details of diet or dosage of insulin, which vary from one person to another. On the whole, diabetes is more severe in young people than in the elderly, but with correct treatment it is possible for all cases to lead a perfectly normal life except in so far as dietary restrictions and insulin injections are concerned. Many famous people are, or have been, diabetics—for example, H. G. Wells—and have lived to a ripe old age. Recently, a drug has been discovered which has the great benefit that, unlike insulin, it can be taken by mouth.

Whereas the type of diabetes we have been describing, the disease ordinarily known by that name, is properly known as *diabetes mellitus*, there is another disease known as *diabetes insipidus*, which, in fact, has no real relation to the other at all. In this disease there is no sugar in the urine, nor has it anything to do with the pancreas. Diabetes insipidus is a rare disease characterised by the passage of large amounts of dilute urine and appears to be due to deficiency of the secretion of the posterior part of the pituitary gland at the base of the brain. It can be partially controlled by the use of pituitrin.

DIET.

Food, like alcohol, tobacco, and constipation, is one of those subjects which people tend to have a "thing" about. In point of fact, what we know at present about this subject may be summarised as follows: Any diet to be adequate must first of all provide enough energy, and energy is measured in terms of Calories (for definition of a Calorie see Gen. Int.). Thus a ten-stone man leading a moderately active life will require about 3,000 Calories daily; that is the amount of energy he requires in order to carry out his work and avoid living on himself, on his stored-up food. The amount of Calories required varies with age, size, and the amount of work done, from 1,500 Calories for the light-weight sedentary worker to three or more times this amount for the heavy manual worker.

Now, in theory, the adequate amount of Calories could be supplied from carbohydrate and fats alone, since, as we have seen, Calories are merely a measure of energy and can be supplied by any food. But in this case the individual would not live long, because he needs for body maintenance certain kinds of food in adequate proportions. Just as you cannot run a car for long simply by putting in petrol and ignoring lubricating oil and maintenance of the engine, so you cannot run your body simply by taking in enough Calories. There must be adequate proportions of the three basic foodstuffs: carbohydrates (the fuel), fats (for insulation and other purposes), and proteins (for body-building purposes). Proteins are necessary to replace the parts of the body, which is largely a protein structure, when they become run-down. In addition to being a ready source of energy, carbohydrate is converted into fat within the body, a fact within the knowledge of everyone, for it is by reducing the consumption of sweets, potatoes, and bread, which are starch and sugar-containing foods, that a tendency to put on weight is reduced. Proteins cannot be manufactured from carbohydrates or fats since proteins contain nitrogen and the others do not. One could even live on a diet of nothing but protein, but not on a diet of fat or sugar; proteins are a biological necessity. It is generally agreed that a well-balanced diet should provide 25 per cent of its energy from fats, 10–15 per cent from proteins, and the remainder, 60–65 per cent, from carbohydrates.

Here are some foods classified according to the predominating basic foodstuff they contain:

(1) *Carbohydrates:* bread, sugar, and all starchy foods or sweet things such as confectionery, puddings, and cakes.

(2) *Fats:* animal fats, such as dripping, fat meat, fried foods, butter, margarine, and vegetable oils, such as olive oil, or fish oils, which are found more in some fish than others —*e.g.*, herring.

(3) *Proteins:* lean meat, cheese, non-fatty fish, nuts, oatmeal.

In addition to these basic foods, the body must also have adequate supplies of vitamins (P42, 62) and certain minerals, such as iron, manganese, calcium, copper, sodium, potassium, iodine, and phosphate.

Obesity. Many people worry because they are overweight, and statistics show that the expectation of life is shorter in fat people than in thin ones. This, however, is a statistical view, and need not apply to any single person. Thus a famous French gourmet who weighed twenty stone died recently at the age of eighty-two—through falling out of a window. When one sees people who are constantly worrying about their health and diet one recalls the statement attributed to Winston Churchill as a recipe for a long life: drink too much, smoke too much, and work hard. He might have added "... and stop worrying." There are few people more pathetic than those who, by rigidly adhering to the so-called rules of health, seek to eke out a life which if it does not actually last longer than that of the more care-free individual, will certainly seem much longer.

Being overweight is due to one cause—eating too much, and especially eating too much of the wrong kinds of food. There are, obviously, some people who can eat to their heart's content without becoming fat, perhaps because their bodies burn up the food more quickly. Their *basal metabolic rate*, which is the measure of the speed at which their body cells work, is higher than normal, and the basal metabolic rate is largely dependent on the functioning of the glands—in particular, the thyroid. Nevertheless, being overweight means that you are eating too much for you; that your intake of Calories is greater than your output.

Reducing is not difficult, but it does require an effort of will. Basically it depends on: (*a*) taking less food, and (*b*) taking food which is not fat producing. In practice, this means taking a high protein diet, little fat, and no sugars or starches. Such a diet would be somewhat as follows: coffee or tea with milk, but *no sugar* for breakfast, and if desired, Energen rolls or Energen crispbread, whether of rye or wheat, but *no white or brown bread*. A small amount of butter or jam may be taken with the crispbread. At lunch, grilled lean steak or an egg dish and salad, followed by jellied or fruit or crispbread and cheese—but *no potatoes*. The evening meal may consist of grilled or steamed fish, clear soup, cheese, fruit, but there must be no fried foods and no sweets at any time. This diet is merely to give an indication of general principles: more interesting ones will be found in the pages of most women's magazines or from time to time in the daily papers. The basic principles are obvious: plenty of lean meat, non-fatty fish, eggs, cheese, fruit, Energen rolls or crispbread (the ordinary crispbread is just as fattening as bread itself), but no fried foods, fat meat or fish, bread, potatoes, sweets, or cakes. However, small amounts of butter and quite a lot of milk are permissible, and the modern tendency is to ignore fat intake which, by reason of its nature, is self-limiting.

Obesity may have a psychological basis, and excessive eating is often a substitute for affection in individuals who have been spoilt as children. But, however this may be, most people find it very difficult to stick to a reducing diet as they do to give up smoking. For such people there are certain drugs which may help. Thyroid tablets, once generally used for reducing, are little used now, and should be used only when the thyroid gland is underactive; otherwise they simply increase appetite, and although they speed up the combustion in the body (the basal metabolic rate) the effect is cancelled out by the increased appetite. Dexedrene, one of the derivatives of benzedrene or amphetamine, acts by reducing the appetite, but in some people of a nervous disposition it may

have the effect of causing a feeling of tenseness, and they may even have difficulty in sleeping. Finally, there is a substance obtainable at chemists' shops without prescription either in the form of granules or biscuits which does not exercise any chemical effect on the body; what it does is to swell up into a gelatinous mass within the stomach under the influence of water, which is drunk later, and this gives the impression of a "full stomach" and allays the pangs of hunger.

There are, as has already been mentioned, many fads about food, although one is treading on dangerous ground when one mentions them; for every faddist is a fanatic, and every argument one may put before him is seen as an attack on himself. For example, there was the "Hay diet," now, it appears, largely forgotten; then the "Gaylord Hauser diet" much favoured by Americans, which seems to be based largely on large quantities of molasses and brewer's yeast: and there was not so long ago a gentleman who lived on grass freshly clipped each morning from Hyde Park—it would be interesting to know whether he has survived his self-imposed ordeal. However, few doctors would deny that, although diet in some cases is an adjunct to the cure of disease (for example, peptic ulcer, diabetes, sprue), it is not a cure for disease, and those who make such claims are claiming a great deal too much. It must be repeated that, so long as a diet contains adequate amounts of the basic foodstuffs, adequate amounts of vitamins and the necessary minerals, and so long as it supplies adequate Calories for the build of the individual and the amount of work he does, it matters very little how these needs are supplied.

Vegetarianism.

This can hardly be called a fad, although it cannot be denied that many of its adherents are faddists. It apparently has two main sources. There are those who abstain from animal food for moral reasons because they believe that killing is wrong, even for food; and there are others who believe that vegetable food is more healthy than animal food. Some vegetarians live almost entirely on vegetables and fruits, whilst others allow themselves milk, eggs, and cheese. The moral issue cannot be argued here, although it must be admitted that few people who have visited a slaughter-house for the first time have as much appetite for their steak the day after, so we shall only discuss the health aspects of vegetarianism. On the negative side, it must be said that, in general, vegetable foods are much less rich in protein than animal foods, so one has to eat a great deal more in order to get an adequate amount. If, however, one includes in a vegetarian diet cheese, milk, and nuts or eggs this difficulty is largely obviated. Cows and other animals living on grass or vegetable matter have to spend practically their whole lives eating, precisely because they would not otherwise get sufficient protein. On the positive side we have the as yet unconfirmed assumption that, in predisposed people over forty, excess of animal fats can lead to cholesterol being deposited in the blood-vessels, notably the coronary vessels in the heart, and thus to coronary thrombosis. Vegetable and fish oils do not seem to have this effect, hence the infrequency of thrombosis amongst those peasants in Europe who are too poor to afford much meat and amongst the Eskimos who eat fish. From the point of view of evolution it would seem that Man is designed to be both carnivorous and vegetarian; for he has sharp, cutting teeth in the front for tearing meat and flat, grinding teeth at the back for dealing with grains. We must conclude that those who are vegetarians for moral reasons should have all our respect; for killing is not a pleasant thing, and we have already too much of it. From the merely medical point of view vegetarianism has both advantages and disadvantages. Nobody will suffer from being vegetarian, but, apart from the exceptions mentioned, there is little reason to suppose that their health will be any better than that of meat-eaters. We are less able to influence our fates than we often suppose, since longevity and good health are much more a matter of heredity than is ordinarily believed.

THE DEFICIENCY AND METABOLIC DISEASES

INTRODUCTION.

If you have read earlier parts of this section you will know that there can be two types of malnutrition; the first, of course, is the type we ordinarily think of when the word is mentioned, and in this case the individual is simply not getting enough food or enough of the right kind of food. The second type might well not be regarded by most people as malnutrition: for here we are referring to diseases such as diabetes and sprue, in which, although there is adequate supply of certain foods, the body, owing to some deficiency, is unable to make use of them. The patient with diabetes cannot make use of sugar, the patient with sprue of fat—they are starving in the midst of plenty, as is shown by the fact that in both cases one of the prominent symptoms is wasting.

We shall deal first with the ordinary type of malnutrition and later with the second. Since diabetes and sprue have already been mentioned, we shall be looking at some other conditions in which something or other is missing or is present in the wrong amounts, as in the diseases of the endocrine glands.

Two-thirds of the population of the entire world are undernourished, and particularly in Asia famines are common—famines like the one in Bengal in 1943, in which 3 million people died of starvation. In Europe such conditions exist only when war dislocates food supplies, but nevertheless individual cases of malnutrition can occur. For example, the lazy or ignorant mother of a large family may feed them largely on bread and margarine, with no fresh fruit or vegetables and only tinned meat because she "can't be bothered" cooking. Or the self-sacrificing mother of a large family may give all the meat and protein food to her working husband (somehow or other many men fail to notice that a housewife works!) and her children. Then old people or people living alone are liable to neglect their food, either because they have lost heart, because they are too frail, or because they cannot afford to buy enough good food. Lastly, those who are addicted to alcohol neglect their food and, drinking on an empty stomach, soon get such a degree of gastritis that they find it difficult to eat even when they need to.

A human being can live about six weeks without food, and a much shorter time—a week or ten days—without water. Naturally, human nature being as it is, there have been many claims to longer periods of starvation, and some of the more enthusiastic claim not to eat at all! Thus, in the sixteenth century Eve Fliegen of Brabant appears to have lived for fourteen years solely on the smell of a rose, and, coming nearer our own time, Mollie Fancher of Brooklyn, who died in 1916, similarly lived for fourteen years without eating, and in 1864 even stopped breathing. However, presumably becoming bored with this, she resumed her respirations after only fourteen weeks.

These people, needless to say, were humbugs, as is revealed by the grim case of Sarah Jacob "the Welsh Fasting Girl," who towards the end of last century allegedly took no nourishment whatever for two years, two months, and one week. The one week, at any rate, is certain; for, at the invitation of the local vicar, who was convinced of her genuineness, a number of doctors from London came to observe her. They put relays of nurses to sit by her bed day and night to note whether she ate, but in a few days she began to decline so alarmingly that the doctors begged the parents to feed her. This they refused to do, and Sarah would not ask for food. She died within a week on December 17th. The most famous non-eater of today is Theresa Neumann, who lives in Bavaria and claims that nothing but the wafer, the Eucharist, at Holy Communion has passed her lips since 1927. The Roman Catholic Church, however, has been careful never officially to recognise her claims as true. So we shall still assert that six weeks, more or less, is the longest period a human being can go without eating.

DEFICIENCY DISEASES.

The materials which are necessary to the body have been mentioned elsewhere, and we can

now look at some of the diseases (other than those already discussed) which result from their lack.

Lack of iron leads to anæmia, but less well known is the type of deficiency caused by lack of iodine. Iodine is found in large amounts in seaweed, which obtains it from the sea surrounding it and concentrates it in its fronds. But ordinary water contains enough for our needs. In some districts, however, especially where the main rock is limestone—Derbyshire and some valleys in Switzerland and the Himalayas—the water contains very little iodine, and there the inhabitants are prone to develop goitre. There are several types of goitre, but this type is caused by lack of the iodine which is necessary to build up thyroxin, the secretion of the thyroid gland. It is a deficiency goitre known in adults as myxœdema, but in those parts where iodine is lacking in the water supplies the disease develops in childhood and the children become, although perfectly normal when born, dull, gross, and stupid—they become idiots or, as they are more correctly described, cretins. This is one of the commonest types of mental deficiency in children, and, if noted in time, they can become completely normal by the use of thyroxin or thyroid tablets. But prevention is better than cure, and this terrible disease has now been almost eliminated in the districts where it used to be prevalent by adding iodine to the water supply of towns and villages, by giving iodised chocolate at schools, or otherwise supplying the missing element.

In this country cretinism and myxœdema are found in individual cases for reasons other than lack of iodine: in children, cretinism may be due to congenital lack of the thyroid gland or early failure, in adults myxœdema may occur when the gland, usually in the middle period of life, runs down. Both conditions can be treated by thyroid tablets, which, like insulin, have to be taken for the rest of the patient's life.

Lack of calcium is less common in this country than it once was. Calcium is necessary for building the bones: it is calcium, in fact, that makes the bones hard. Actual lack of calcium in the diet is very rare, because calcium is one of the commonest elements in Nature, and what usually happens is that lack of vitamin D or calciferol, without which calcium cannot be utilised or absorbed, causes the deficiency.

The two main diseases caused by calcium, or rather vitamin D, deficiency are rickets and osteomalacia. Vitamin D is found in fats—but only animal fats such as are found in meat, fish, and milk; it is not found in vegetables, plants, or fruit. A second source of the vitamin is sunshine or ultra-violet light, which manufactures it in the skin; hence, in spite of inferior diet, rickets and osteomalacia are perhaps less common in sunny countries. In *rickets*, a child during the period when its bones are developing does not get enough vitamin D and cannot make use of the calcium taken in. Its bones become soft and are liable to bend, producing defects such as bow legs, curvature of the spine, and deformities of the chest (pigeon chest, funnel chest). In bad cases the skull is deformed and assumes a square shape. Rickets is rare today, at least in Britain; it is prevented by taking vitamin-D-rich oils, such as cod- or halibut-liver oil, or the vitamin can be taken in a more or less pure form in capsules.

In these days when diets are adequate, when children get cod-liver oil at home or school, and when they are much more often in the sunshine than used to be the case, it is not always realised that *overdosage* of vitamins, especially vitamin D, is possible. In its extreme form this is a rare condition, but children have died from overdoses which caused calcium to be laid down where it did not belong—in the kidneys and elsewhere. It is possible to have too much of anything.

Rickets is uncommon in adult life because the demand for calcium is less than in the growing child. But in pregnancy the demand increases, and especially in Eastern lands, where famine is frequent and where, although there is plenty of sunshine, the women are veiled from any of the sun's rays, there may occur the disease of *osteomalacia*. In this disease the bones soften and deformities occur which are particularly important in the case of women, in whom the pelvis becomes deformed, with resultant difficulties in child-birth. Osteomalacia is a main cause of the high maternal and infant mortality in such countries as India.

In old people who do not get enough food, lack of vitamin D causes no deformity, but leads to the condition known as *osteoporosis*, in which the bones, through lack of available calcium, become brittle and break easily.

Scurvy is another once-common deficiency disease which is now rare except under such unusual conditions (or perhaps not so unusual in these days) as life in concentration camps or amongst prisoners-of-war. It is due to lack of vitamin C, which is found in fruits and vegetables, particularly in lemons, oranges, tomatoes, and turnips. In scurvy the gums swell and bleed, there is increasing anæmia, and spontaneous bruises, due to hæmorrhage under the skin, occur. In former times the disease was the bugbear of sailors and travellers, because on long journeys or voyages before means of preserving food were known other than drying or salting no fresh fruit was available. It was no less a personality than Captain Cook who on his long voyages found that the simple use of lemons or limes would prevent the disease. Hence the almost international description of Englishmen as "Limeys"—a name which is not always used flatteringly, but of which we have every reason to be proud. Minor degrees of scurvy may occur in British children even today, through faulty diet, but this is much less common since orange, blackcurrant, or rose-hips syrup became available to all.

We now come to the B group of vitamins. There are, regrettably, many members of the vitamin B family, but we shall mainly deal with vitamins B1 and B2.

Beri-beri is caused by lack of vitamin B1, which is found in most grains, principally in the embryo and the outer covering. Now, since many people are snobs, who prefer white bread to wholemeal and polished rice to the crude article, it has become the habit to remove the precious outer covering of the grain and its embryo which contain the vitamin: white bread and polished rice *look* so much better. Thus, in those parts of Asia where rice is the staple diet, it was frequently machine milled, with loss of the vitamin, and the result was the serious form of neuritis known as beri-beri. Just as Captain Cook eradicated scurvy from his men by the use of citrus fruits, so, in 1882, Takaki eliminated beri-beri from the Japanese Navy by giving a good mixed diet. This led two Dutchmen, Eijkman and Grijns, to study the disease experimentally. They found that fowls fed on polished rice developed the disease, whereas those fed on rice with the husk did not. In this country we are still in the rather foolish position of carefully removing the vitamin by "refining" the flour and then replacing it chemically. However, although wholemeal bread is probably better, there is really little risk of an European diet lacking vitamin B1.

The symptoms of beri-beri are neuritis (*i.e.* degeneration of the nerves), which leads to weakness of the muscles, wasting, and sensations of "pins and needles"; the heart muscle is also affected and œdema—swelling of the limbs—or ascities (fluid in the abdomen) occurs.

Pellagra. Vitamin B2, or rather the vitamin of the B2 group, of which the main ones are riboflavin and nicotinic acid, is another substance deficiency of which in this case leads to pellagra. Pellagra is found in those parts of the world where maize is a staple diet, that is in parts of America and the Far East and round the Mediterranean. Maize does not contain the vitamin which, like vitamin B1, is found in most other grains and vegetables, but since vitamin B2 is also normally produced by the action of bacteria in the human colon, it would appear that there is some other factor than the mere absence of the substance from the diet. Probably maize contains a substance which prevents the absorption of the vitamin from the colon.

In pellagra there is wasting, soreness of the mouth, diarrhœa, skin rashes on the hands, forearms, face, and neck. In severe cases insanity

may occur. The disease does not occur in this country in its full-blown form, but minor degrees may develop with the use of certain antibiotics, such as chloramphenicol and aureomycin, which kill the "good" vitamin-producing bacteria in the intestine as well as the disease-producing ones.

Vitamins.

Whereas vitamins B and C are found mainly in vegetables and fruits, vitamins A and D are found in oils and fats. Vitamin A is, indeed, found in the form of carotene in all green vegetables, but it is not much use to us until it has become concentrated in the fat and milk of the animals who eat the vegetables. Lack of the vitamin leads to *night-blindness*, to difficulty in seeing in the dusk. This is because the retina, the "mirror" at the back of the eye, requires adequate amounts of a substance known as visual purple for its full efficiency, and visual purple is manufactured from vitamin A. (It must be noted, however, that not all cases of night-blindness are due to lack of vitamin A—there is often a very large neurotic element, and it was frequently found during the War that men who on this account pleaded their inability to carry out sentry duties at night might show a very considerable talent for seeing their girl-friend at the camp gate even in pitch darkness.) Vitamin A is also connected with the health of the skin and the ability of the body to resist diseases of the respiratory tract such as bronchitis. Like vitamin D, it is most easily obtained from fish oils, such as halibut-liver oil.

Lesser-known vitamins are vitamins E and K. The former, found in wheat-germ oil, influences fertility; the latter influences the clotting power of the blood and the healing of wounds. Most vitamins can now be produced in the laboratory synthetically; in the case of vitamin B1 from coal-tar.

It is important to realise that vitamins, although necessary to health, are not cure-alls. There are few sights more ridiculous than the fad of over-fed individuals taking vitamin pills as a tonic to keep themselves up to scratch. Any vitamins taken in excess of requirements may either cause damage —as in the case of vitamin D—or else are simply excreted from the body. Extra vitamins are not a tonic, those who take them in excess are simply wasting their money, and if one eats a good mixed diet they are totally unnecessary.

GLANDULAR DISEASES.

The Endocrine Glands.

The workings of the body are regulated in all sorts of different ways—by the nervous system, the circulation, and by the endocrine glands or ductless glands, as they are sometimes called. We have already seen that there are glands, such as the liver (the largest gland in the body) and the pancreas, which manufacture substances and pass them through a duct or tube to their destination. But the ductless glands, as their name implies, have no duct and pass their secretion directly into the blood; the pancreas, for example, discharges the pancreatic fluid down a duct, but it also produces insulin, which is secreted directly into the blood. It is thus partly an endocrine gland and partly an ordinary one. The other endocrine glands are particularly important in that they produce hormones (the word means "chemical messenger"), which have a great deal to do with personality and health.

Myxœdema, we saw, is due to lack of thyroid hormone either because the gland, which is at the base of the neck astride the windpipe, has failed or because it has insufficient iodine to manufacture its product. The opposite effect occurs when the gland becomes overactive, and then we get a quite different state of affairs: instead of being dull, slow-witted, and flabby-looking, the patient with an overactive gland—*exophthalmic goitre* or *thyrotoxicosis* is excitable, nervous, flushed and thin. The eyes become prominent and bulge forward, giving a startled, scared look. The disease is commonest in young adults, mostly women, and its origin is often associated with an emotional shock. Thyrotoxicosis is not primarily a disorder of the thyroid gland, and it is likely that the sequence of events is: emotional shock, which influences the nerves supplying the pituitary gland at the base of the brain, overactivity of the pituitary with over-production of the hormones, which in turn affect the thyroid. (The pituitary is the main endocrine gland in the body and gives off hormones which control all the other glands—it has been called the "conductor of the endocrine orchestra.") All the body processes—the basal metabolism—are speeded up in this disease, which, however, cannot be treated at its roots in the pituitary. Sometimes it can be treated medically by the drug thiouracil, which damps down the activity of the thyroid, but more usually an operation is necessary to remove part of the gland. It is also possible in suitable cases to give the patient radioactive iodine—a radio-isotope which is carried, as all iodine is, to the gland, where it destroys some of the overactive tissues. The results of these procedures are good, but any exophthalmos, the prominence of the eyes, which may be present always remains.

A similar condition appearing in the middle age, may result, not from shock or from an overall enlargement of the gland, but from a *toxic adenoma*, which is a simple, non-malignant tumour. In this case exopthalmos does not occur, but the tumour should be removed. Malignant tumours also occur.

The Parathyroid Glands.

We have already discussed the importance of calcium in the body and seen how vitamin D is necessary for its utilisation. But the calcium content of the body is controlled by another factor, the parathyroid glands—two pairs of small glands lying behind the thyroid. Now calcium, in addition to building the hard structure of bones, has another function in that it acts as a kind of sedative, damping down nerves and preventing overexcitability. When the parathyroid glands do not work properly, or when they have been partially removed during a thyroid operation, *tetany* (not to be confused with tetanus) arises. The hands and feet go into spasm and there may be generalised convulsions. Tetany can be produced in a number of other ways which influence the amount of calcium in the blood: for example, alkalosis when people have taken too much alkali for stomach disease, or when they have lost acid through persistent vomiting, or even by overbreathing—*i.e.*, persistent deep and rapid breathing, which causes the body to lose carbon dioxide—a condition which may occur in hysterical or neurotic patients. The treatment is to give large amounts of calcium and vitamin D.

Overactivity of the parathyroid glands, usually due to a tumour, causes the reverse effects. The blood calcium is high, but this calcium has been withdrawn from bones, and a disease known as *generalised osteitis fibrosa* arises, in which the bones become soft and there is pain, fractures, and deformities. Sometimes cysts form in the bones. The treatment is operative removal of the tumour.

Salt is very important in the running of our bodies. Indeed our blood has been described as an "inner sea"; for, whereas primitive creatures in the ocean, such as sea-anemones and sponges, get their sustenance from the sea surrounding them and do not need a blood-stream within, in the course of evolution the situation gradually changed. As sea-animals grew bigger, the water outside did not suffice, and they had to develop some sort of circulation within; even more so, when they developed into land animals they had to carry their sea about with them. Loss of the salt in this inner ocean is occurring all the time, both through the urine and through sweating. Workers who do heavy jobs in a hot atmosphere lose a great deal of salt through sweating, and if afterwards they drink a great deal of water the remaining salt in the body becomes even more diluted, with the result that they will get painful cramps. Similarly, diarrhœa or prolonged vomiting can bring about the same result through

loss of salt from the body. After long periods of exercise it is much more refreshing to take water with added salt than to take pure water, which will increase rather than diminish our fatigue.

Suprarenal Glands.

A glandular disease which influences the balance of salt in the body is *Addison's disease*, named after the famous English physician who first described it. This disease is characterised by great weakness of the muscles, tiredness, loss of weight, low blood-pressure, and a brown pigmentation of the skin. Until recently it was always fatal. Addison's disease is caused by damage to the suprarenal glands, two small glands which sit one on top of each kidney like little cocked hats. These glands produce a number of hormones, one of which controls the excretion of salt from the body; if it is lacking, too much salt escapes, with the results described above. The disease is now treatable by the use of cortisone, one of the suprarenal hormones.

These glands consist of an inner part or medulla which secretes a hormone known as adrenalin—the substance which, when released into the blood, prepares us for states of emergency. It reinforces states of anger or fear, and aids in the process of fighting back or running away. The cortex (the word means " bark of a tree "), on the other hand, secretes a number of hormones, one of which, as we have seen, is connected with the salt content of the body and another which plays some part in sexual development. Thus a tumour of this area may bring about a state of *hyperadrenia*, in which excessive secretion leads to premature or excessive development of masculine sexual traits. Boys show precocious sexual development, their voice breaks, and their muscular development increases. Girls assume male characteristics. This is known as the *adreno-genital syndrome*.

The Pituitary Gland.

The pituitary gland, lying at the base of the brain, is only about the size of a small cherry, yet it not only regulates the behaviour of all the other glands but is responsible for sexual development and growth. It consists of two parts, the anterior (which does all the interesting things), and the posterior, which secretes a hormone known as pituitrin, thus raising the blood-pressure and causing the muscle of the uterus to contract. Many conditions are described in which the anterior part of the gland either produces too much or too little of its hormones. For example, when this part overacts in early life the result is a giant—*i.e.*, anyone over 6 ft. 8 in. In later life, when the bones are set, the result of overaction is *acromegaly*, in which the face is elongated, the hands are relatively huge, as also are the feet. The head, too, is large, and the patient gives a somewhat gorilla-like impression.

When the anterior part of the pituitary underacts there are many unpleasant possibilities: the individual may develop into a fat boy, like the one in *Pickwick Papers*, sleepy, greedy, and monstrously fat; or into a human skeleton who appears to have hardly any flesh at all; or there may develop painful masses of fat in the wrong places, a condition described as *adiposis dolorosa*; or again, dwarfism may result and the individual retain the appearance and size of a child with normal adult mentality. These conditions are known by the various names of *Frölich's syndrome* in the fat-boy type, *Simmond's disease* in the human skeleton, *Dercum's disease* in the case of adiposis dolorosa, and *Lorrain's disease* in the case of dwarfism.

The Sex Glands.

In women these are the ovaries, and in man the testes. The ovaries produce two hormones, one of which, œstrin, brings about, under the influence of the pituitary, the normal sex changes at puberty, controls the release of the ovum from the ovary, and, in animals, produces sexual excitement. The other, also controlled by the pituitary, is progesterone, which in general has a sedative effect: it prepares the uterus for pregnancy, an when a pregnancy exists, maintains it.

The internal secretion of the male sex glands testesterone, and it, like œstrin, produces the s changes at puberty. The problems of se however, will be discussed later.

DISEASES OF THE URINARY SYSTEM.

Everyone knows what kidneys look like—fact, the term " kidney-shaped " is used to de cribe other objects. Within the kidneys the bloo vessels carrying waste materials subdivide a finally end up in little coils or glomeruli throu which waste products are filtered into the oth system, the system of tubules which, beginning tiny cups around the glomeruli, become larg and larger until they join the ureter passing o at the root of the kidney, the hilum, a point which both the veins and tubes enter and leav The kidneys, of course, lie one on each side in t loins, so that if one puts one's hands on the hi and then slides them farther back they will cov the area over the left and right kidney. T ureters pass down on each side to the bladd which is the storage tank of the products excret by the kidneys, and lies in the mid-line down lo in the abdomen; it is somewhat pear-shaped, a at its base in men there lies the prostate gland a gland which apparently has few functions b can be a nuisance if its normal function that it adds something to the semen from t testes without which the semen would be steri Then, from the base of the bladder a single tub the urethra, passes to the outside. One can, fact, visualise the urinary system as a capital in which the two upper limbs are the ureters, t place where they meet is the bladder, and t single limb at the foot is the urethra. Clearl then, there may be diseases of the kidneys, the ureters, of the bladder, of the prostate glan or of the urethra.

The amount of urine may be increased diminished. It is *increased* in the followi conditions: after drinking excess of fluids; aft taking drugs (known as *diuretics*) which a given to increase the flow; in diabetes of bo types—mellitus and insipidus; in some types chronic kidney disease; and finally, in emotion states of excitement. It is *decreased* in t following conditions: acute nephritis; any d ease in which fluid is being lost in other wa such as diarrhœa or sweating in fevers; when t fluid intake is small; and when both ureters a blocked by stones. Passing a great deal of uri is known as *polyuria*, passing very little *oliguoria*, passing frequent small amounts simply called *frequency*. Normally, the urine acid, but in infections of the bladder it m become alkaline owing to decomposition b bacteria. Abnormal substances, or norm substances in abnormal quantities, may occur the urine and give the doctor an indication what is wrong. In fact, urine analysis is a ve important part of medical diagnosis. Thus ur is a normal content of urine which is increased fevers, wasting diseases, or diabetes; the amou of urea is to some extent a measure of the degr of tissue breakdown. Uric acid is found in sm quantities in normal urine, but the amount increased in fevers and after an attack of go (uric acid is important in the causation gout, but has nothing at all to do with rheum tism in general, so one may disregard the a vertisements in the popular Press showi unpleasant pictures of joints with sharp cryst of uric acid which are alleged to cause the pain rheumatic disease). Oxalates are not ordinar found in urine, but, since they occur in such foo as rhubarb and strawberries, and some people a unable to deal with them, such individuals m develop stones or have pain on passing urine af eating oxalate-containing fruits.

Two very important substances which oug not to be in normal urine are albumen and sug Albumen is a protein, and its presence in the uri indicates that the filters of the kidney are leaki —they are allowing protein to pass out whi ought to remain in the body. Albumen is eas tested for, and its presence may indicate kidn disease or nephritis as it is usually called doctors. On the other hand, small amounts

albumen occur in fevers and in nervous conditions —*functional albuminuria*. Sugar, too, should not be present, but its presence does not necessarily indicate diabetes; for small amounts may occur in nervous conditions or in some people after taking large quantities of carbohydrate.

Blood in the urine may give it an appearance which varies from bright red to a dark, smoky colour. It is found in many diseases: acute nephritis, stone, tumours, poisoning by certain drugs, infections such as bilharzia or malaria, papilloma (*i.e.*, non-malignant tumour of the bladder), after injury, in high blood-pressure, scurvy, and blood diseases. Sometimes it occurs for no known reason at all.

It will be remembered (or if it is not, you can look it up on p. 28 (1)) that streptococcal infection of the throat may cause in some people disease of the valves in the heart or endocarditis. In such cases, although the germ is found in the throat, it is not found in the heart or indeed anywhere else in the body. *Acute nephritis* occurs in the same circumstances, with the sole difference that the kidneys instead of the heart are affected. The disease appears to be an allergic reaction to the toxins of the streptococcus. The patient, often a child, has a sore throat (and even this may be absent or fail to be noticed) or sometimes the infection may arise in other sites: after scarlet fever, erysipelas, burns, and disease of the ear. A few days later there is headache, vomiting, pain in the loins, slight rise in temperature, and especially typical is *dropsy* or œdema. This begins in the face, the skin round the eyelids, and then affects the ankles; later it may become more general and affect the rest of the body. Blood and albumen are found in the urine, and the blood-pressure is slightly raised. The outlook is usually good if the kidneys are rested by reducing the amount of protein taken in and also the amounts of salt and water. When this is done, the inflammation soon goes and no permanent harm results. In other cases, however, if treatment is inadequate or the condition severe, the symptoms may go, but the albumen found in the urine persists. This means that permanent damage has been done, and although there may be nothing else to show for many years, *chronic nephritis* develops. In this case, the blood-pressure continues to rise, and since the filters of the kidneys no longer work efficiently, urea, the principal waste-product of the body to be excreted in the urine, is retained in the blood and only small amounts escape from the system. Hence chronic nephritis sooner or later leads to heart failure or hæmorrhage in the brain from the rising blood-pressure, or to the form of poisoning known as *uræmia* which results from the retention of urea in the blood. Uræmia may come on suddenly or gradually, but ends in progressive coma, drowsiness, and unconsciousness. There may be convulsions similar to those of epilepsy, high fever, and difficulty in breathing to complicate the picture.

Another type of nephritis which seems to have nothing at all to do with streptococcal infections, and the cause of which is completely unknown, is *nephrosis*. Developing in early adult life, its onset is insidious, and the patient first shows signs of œdema in his white and puffy face and the swelling of his legs. (It should be said here that if you have swelling of the ankles or elsewhere, you would be foolish to jump to conclusions; for such swelling is common in many diseases—in heart disease, in allergic conditions, in neurotic illness, and even just from hot weather.) When the urine is examined in a case of nephrosis it is found to be full of albumen and, as in chronic nephritis, the blood urea starts to rise. The end-results of nephrosis are the same as those of chronic nephritis and depend upon the damage originally done.

The modern diuretics of the chlorothiazide group help to control the œdema and, provided enough healthy tissue remains, remove both the fluid and the waste-products. In advanced or more serious cases artificial kidneys can be used, but as yet the transplantation of a kidney is largely in the experimental stage.

Pyelitis is an infection of the pelvis of the kidney, that is to say, of the part where the ureter leaves the kidney. It is usually caused by the bacillus coli, which is normally present in the body, or by the streptococcus. These germs may reach the ureter through the blood-stream or may pass upwards from the bladder. Obstruction anywhere in the urinary tract which causes the urine to stagnate is liable to cause pyelitis. Symptoms come on suddenly, with high fever, pain in the loin (the infection is usually on one side only, and is commoner in women), and pain in the abdomen. When urine is passed there is a burning sensation, and it is passed frequently and in small amounts. On examination, the urine is found to be highly acid and full of bacillus coli or whatever the causative germ may be. Pyelitis is fairly readily treated by the antibiotics or sulpha drugs. Plenty of fluids should be given and the urine made alkaline by administration of alkalis.

Cystitis means inflammation of the bladder, either acute or chronic, and its causes are much the same as in the case of pyelitis. There is pain over the lower abdomen, frequency, and sometimes slight fever. The treatment is as for pyelitis. *Urethritis* is an inflammation of the urethra, with burning pain on passing water and frequency. The most serious cause (although it can usually be easily dealt with now) is gonorrhœa. But non-specific urethritis is common, and in this case various germs or none may bring about pain and frequency; there is often a large neurotic element. Urethritis should be regarded as probably due to gonorrhœa, which has already been discussed elsewhere, when there is a thick, creamy discharge from the penis or discharge in women following sexual intercourse with an infected person.

Kidney stones or Renal calculi sometimes form, and, as in the case of gall-stones, what causes them is not certain. They may be caused by disorders of metabolism—that is, in the inability of the body to deal with calcium, proteins, uric acid, and other products; or by vitamin deficiency obstruction in the urinary tract, and urinary infections. But when a stone or stones are formed various events may occur: thus it may remain in the kidney and cause no symptoms; or it may cause repeated attacks of pain, infection, and blood in the urine (hæmaturia); or it may completely block the passage of urine from the kidney to such a degree that it degenerates and becomes useless; or, lastly, it may pass into the ureter, and when this occurs very severe pain, known as *renal colic*, will occur. A stone passing down the ureter into the bladder may become stuck in the urethra, although this is uncommon, since a stone small enough to get down the ureters is likely to be capable of manœuvring through the rest of the tract. In fact, about 80–90 per cent. of stones are passed spontaneously. Stones not passed spontaneously may have to be removed by operation, but whether this is undertaken or not depends on various factors, such as the general health of the patient, the amount of trouble caused by the stone, and the health of the other kidney —for it is dangerous to operate on one kidney unless one is sure that the other is functioning efficiently.

If a stone blocks the passage of urine on one side for any length of time *hydronephrosis* may result, in which the part where the ureter enters the kidney swells with the retained urine. Ultimately much of the kidney may be destroyed by the back-pressure. The same effect may be produced by kinking of the ureter or anything else which causes obstruction. Sometimes children are born with hydronephrosis, and when the dilation is due to kinking of the tube the condition may be intermittent, with attacks of renal colic during which only small amounts of urine are passed; this is followed with relief and the passage of large quantities.

Tumours and Cysts. The kidney may also be the site of tumours and cysts which produce pain in the loins, sometimes a lump over the kidney which can be felt, and blood in the urine. Cancer of the bladder is a serious condition in which the bladder may have to be removed, so the urinary flow has then to be directed elsewhere. Either the ureters are brought out on to the skin surface, a procedure known as *cutaneous ureterostomy*, or they are implanted in the large bowel, so that the urine flows out with the fæces. This is described as *uretero-colostomy*.

There may also be benign tumours of the bladder or *papillomas*, which are soft and bleed easily; a great deal of blood is passed, but there is usually little or no pain. In this, and similar, diseases of the bladder examination of the inside of the organ is carried out by means of a cystoscope, a thin tube which is passed up the urethra and has a small electric light at the end which enables the surgeon to see what is going on. Instruments may also be passed through the tube, and simple papillomas can be cauterised. Similar instruments are used in the examination of the stomach (gastroscope) and the bronchial tubes (bronchoscope). When some obstruction in the outlet of the bladder or in the urethra occurs the bladder, of course, fills with urine, which cannot be passed, and very painful dilation occurs. In this case an attempt may be made to pass a catheter, a thin rubber tube, into the bladder to relieve the tension, or if this fails a *suprapubic cystomy* is performed—an incision is made in the abdomen over the bladder and a tube inserted into it, through which the urine escapes. This is ordinarily a temporary expedient, and later when the patient's health has improved an attempt will be made to remove the cause of obstruction. The most common cause of such obstruction is *enlargement of the prostate gland* at the base of the bladder, which surrounds this area and the beginning of the ureter. About 40 per cent. of men over sixty have some degree of obstruction due to this cause, and about 20 per cent. of these require operation. The gland is about the size of a walnut, and, as we have seen, its function is to supply part of the fluid which makes up the semen, the male sex secretion. Enlargement of the prostate may be benign or malignant, and, although nobody knows just why, such benign enlargement tends to occur in most men in later life. There may be no symptoms, but characteristically there is frequency during the day and the need to get up at night to pass water. The flow of urine being impeded by constriction of the urethra, the passage is less forceful than normal, and there is a tendency for dribbling to occur. If the obstruction is severe and not relieved the back-pressure may be transmitted to the ureters and kidneys, resulting finally in kidney failure and uræmia. The prostate, except in cases of very mild enlargement, has to be removed either through the abdomen or through the perineum (the part of the body lying between the sex organs and the anus). Sometimes, in less serious cases, it is possible without an incision to cut away the obstructing part by an electrocautery inserted, as is a cystoscope, through the urethra. Prostatectomy was once a serious operation, all the more so because the patient was usually elderly and not in good condition, but new techniques and the use of antibiotics have greatly improved the outlook.

Cancer of the Prostate is always serious, but if discovered in time it can be operated on successfully. The gland, of course, has to be completely removed; in inoperable cases, or in patients unfit to stand operation, the tumour may be treated by means of female sex hormones, which cause it to shrink and may prolong life by some years.

DISEASES OF THE NERVOUS SYSTEM.

The brain and nervous system are like a telephone exchange which sends out and receives messages from the rest of the body. Essentially it consists of two levels, the lower centres, where primitive emotions are felt, the viscera controlled, and simple actions initiated, and the true brain, which holds the lower centres under control. When, for example, one is pricked with a pin, a message is passed up the nerves (the sensory nerves or nerves of feeling) to the lower centres in the spinal cord, which return a message through the motor nerves (the nerves dealing with movement), causing the hand to jerk away. All this takes place without any conscious interference, and can, in fact, happen even when the true brain has been removed. It is, of course, possible for the movement which jerks the hand away to be inhibited, because in this case the brain intervenes; all mental life is a constant interaction between the lower and higher centres. When we become angry, for instance, the ang originates in the lower centres, but may be i hibited by the higher ones. To some extent, t former correspond to what a psychologist wou describe as the unconscious mind, the latter the conscious mind.

The nervous system is made up of nerve ce which are smaller than the head of a pin but e in a long, thin fibre, which may be several fe long. These fibres form the nerves of the bod and they end in the motor nerves, which bri about muscular movement, or in the skin, whe there are separate nerve-endings dealing wi pressure, heat, cold, pain, and so on. It used be supposed that there were areas in the bra dealing with such mental faculties as acquisitiv ness, conscientiousness, and other abilities; b this is known to be quite untrue. There a indeed, areas dealing with movement, sigh hearing, speech, feeling, and thought, but c tainly none dealing specifically with the m complex mental faculties. Nor is it correct suppose that each nerve cell carries some particu thought or feeling; for it appears that thinki and feeling are represented by nervous circuits the brain and are not isolated in any special ar Thus large parts of the brain can be remov without interfering with mental activity.

The most primitive part of the nervous syst is the autonomic nervous system, which has "brain" in the hypothalamus at the base of t true brain. It is divided into two parts: t sympathetic nervous system, which supplies viscera with impulses which prepare the body flight or fight (causing the heart to beat fast the muscles to become congested with blood, skin to become pale, and the blood-sugar to whilst the intestines become less active), and parasympathetic nervous system, which, general, produces relaxation. When the pa sympathetic system acts, the heart beats m slowly, the skin becomes flushed, the intesti digest food, and the body is prepared for re Since, as we have seen, the lower centres are centres controlling both emotion and the inter organs, it is clear that emotional states influence the action of the body. This is basis of psychosomatic medicine.

The brain and the spinal cord, which pas down the bony canal within the spine, are cove with a thin layer of tissue known as the menin and surrounded with cerebro-spinal fluid, wh is also found in the cavities of the brain known ventricles. A specimen of cerebro-spinal flu or C.S.F., may be removed by pushing a hol needle between the vertebræ in the lumbar regi and such specimens can give a great deal information about what is going on in the nerv system.

The diseases of the nervous system can divided into various groups: there are those to injuries, such as fractures of the skull or divi nerves; the infectious diseases, most of wh have been discussed already; the diseases due hæmorrhage or embolism; tumours; and, perh the biggest group, the degenerative diseases.

The blood-vessels of the brain are one of common sites of *aneurisms*, bulges like sm berries, often at the base of the brain, caused weakness of the vessel wall. This is sometir the result of arteriosclerosis, syphilitis infecti or injury, but perhaps most often the aneuris are congenital—*i.e.*, the individual is born w them. There are usually no symptoms, altho if the aneurism is large enough it may press u other structures and cause symptoms recognisa by the specialist. In most cases the diagnosi apparent only when the aneurism, as may occ ruptures. When this happens the symptoms those of brain hæmorrhage. There is sev headache, vomiting, and loss of consciousn the patient breathes heavily, and when the doc does a lumbar puncture the C.S.F. is stained w blood. Such an event is very serious, ordinarily all that can be done is to rest patient; nevertheless, over 60 per cent. of ca are fatal.

When in the few cases in which sympto occur *before* hæmorrhage, the presence of aneurism is suspected, this may be confirmed X-ray. Since soft tissues are not seen in X- pictures, it is necessary (for example, in the g

bladder, the kidneys, the bronchi, or the blood-vessels of the brain) to inject some radio-opaque substance which outlines them. In the brain this is known as arteriography, and when by this means aneurisms or other abnormalities are found surgery is sometimes possible. Hæmorrhage into the brain substance produces what is generally known as a *stroke*. The artery affected is usually the middle cerebral, when in later adult life it has been strained and weakened by high blood-pressure or arteriosclerosis. It can, however, be caused by bleeding into a tumour, or in children by birth injuries. Hæmorrhages may also result in the small veins from the strain of coughing in whooping cough.

A stroke comes on suddenly, and the patient is flushed with a bluish tinge. He breathes heavily and, as he breathes, the cheek on the affected side may be blown in and out. Since the left side of the brain supplies the right side of the body, and *vice versa*, the side of the body on the opposite side from hæmorrhage is paralysed. The limbs and face right down the affected area are flaccid and useless, but if the patient survives they will at a later stage become spastic. There are, therefore, two types of paralysis: flaccid and spastic. In the first, the limb is incapable of movement, and when lifted it falls back like a dead weight; there are no reflexes, so that when the knee-cap is tapped to elicit the knee-jerk there is no response. Flaccid paralysis is typical of injury to the lower parts of the nervous system, and it means that no impulses are getting through. Spastic paralysis, on the contrary, is characterised by rigidity of the limb, overactive reflexes, and even when movement is possible it is out of control. This, in fact, is what has occurred; for spastic paralysis indicates that, although the lower nerves are undamaged, the controlling centre in the brain has been affected.

If the patient survives, there may be varying degrees of improvement in the paralysis, which is always at its greatest in the beginning.

When such an emergency occurs it is best to leave the patient where he is, keep him warm, take out his dentures if any, call the doctor, and on no account to give him any fluids or alcohol. No patient in coma should ever have fluids poured down his throat. Other causes of coma are diabetes, alcohol, uræmia, acute hypertensive (high blood-pressure) attacks, and thrombosis or embolism.

In thrombosis and embolism a similar picture to that of hæmorrhage occurs. Embolism comes on suddenly like a hæmorrhage, but in thrombosis or clotting the onset may be more gradual, with premonitory symptoms of headache, giddiness, and numbness or pins and needles in the limbs. There may be difficulty in speaking.

Tumours and Abscesses. The brain is soft, greyish white in colour, and from the upper surface closely resembles a huge walnut in that it has two sides joined across the middle by a smaller part known, in the brain, as the corpus callosum. It resembles a walnut, too, in that its surface is crumpled up into convolutions. Investigation of the brain has become more and more refined in recent years, the following being some of the techniques employed:

(1) Straight X-rays.

(2) Arteriograms, which have already been described.

(3) Encephalograms or ventriculograms, in which some of the fluid, the C.S.F. surrounding the brain or in the cavities known as ventricles within the brain substance, is removed and replaced by gas. The gas may be helium or oxygen, and it has the effect in an X-ray picture of outlining the brain and ventricles so that any distortion of shape due to a tumour or abscess is outlined.

(4) Electroencephalograms are pictures made of the electrical brain waves produced by the brain, just as the electrocardiograph takes pictures of the similar waves produced by the heart. Electrodes attached to the scalp may show abnormal waves over the site of a tumour or abscess.

(5) Still more recently, radioisotopes have been used to locate tumours, since radio-active substance become concentrated in the area of the abnormal tissues.

The main symptoms of brain tumour are severe headache, vomiting, and disturbances of vision; such symptoms must be referred to a doctor at once. The pulse-rate is usually slow. All these symptoms are caused by increasing pressure within the brain because of the space taken up by the tumour.

The popular belief that a brain tumour is tantamount to a death warrant is simply untrue; for at least 80–90 per cent. of cases recover. The main types of tumour are meningiomas (*i.e.*, tumours of the brain coverings or meninges); tumours of the nerve fibres within the brain or neurofibromas; tumours of the pituitary gland; and gliomas, which are tumours of the background substance. The outlook for all of these is good, except in the case of the glioma, which is a type of tumour which tends to infiltrate into the rest of the brain fairly rapidly. It is not localised, and therefore complete removal is not always possible.

Brain abscesses may be spread from the blood-stream in people with bronchiectasis, osteomyelitis, infected sinuses, or chronic ear disease. The symptoms are similar to those of tumour, but there is also fever and drowsiness.

Aphasia is a disturbance of the ability to speak, write, or to understand spoken or written words. It is usually due to a tumour, abscess, thrombosis, or embolism of the speech area in the brain. In motor aphasia the muscles of speech are normal, but the patient is unable to speak intelligibly. In nominal aphasia the patient cannot name objects, which he nevertheless is able to recognise. In agraphia the patient cannot write, although his muscles are normal. In word-blindness and word-deafness the patient cannot understand written or spoken words respectively. Treatment depends upon the cause, but in hopeful cases re-education is sometimes possible.

Headaches. This seems a convenient point to say something about headache, which must surely be one of the commonest symptoms suffered by the human race. We shall begin by noting that at least 90 per cent. of all headaches are nervous in origin or the result of such other minor troubles as gastric upset. It is doubtful whether headache is as frequently brought about by eye-strain as is often supposed, but there is certainly no harm in having one's eyes tested if frequent headaches are present.

A doctor will first try to distinguish between headaches due to mental causes and those due to organic or physical ones. When the cause is physical the headache is often very severe, usually located sharply in one area (for example, on one side of the head), and it is likely to be accompanied by other symptoms, such as vomiting and eye-disturbances. The person with this type of pain often tries to minimise the pain he suffers, but his behaviour—for example, his obvious fear of moving his head—belies him. The neurotic person, on the other hand, suffers from headaches which are "terrible," "awful," "unbearable," vague in their location (they are "all over"), and, if they are accompanied by other nervous symptoms, the diagnosis is clear. Apart from the neurotic type, headaches are caused by migraine, increased pressure within the skull, as in brain tumour or abscess, sinus disease, and eye diseases. Treatment obviously depends on the cause, and the sensible thing to do is to go to a doctor, believe what he says, and take his advice. Neurotic headaches may be dealt with by investigation of the sources of worry, frustration, and so on which cause the pain, or by taking aspirin or other pain-relieving drugs. (Pain, in fact, is one of the very few things aspirin is good for, and as has already been said elsewhere, those who believe that it is good for "nerves," insomnia, and all the various conditions which make aspirin an almost universal cure in the minds of many, are deluding themselves.)

Migraine is a disorder which many claim to possess and not so many really do; if all the people who claim this dubious honour—often those who have little better to do than be bored

with themselves—if all these were put end to end, or even stood upright in a line, they would surely encircle the Earth. True migraine, however, is a very clear-cut disease, and happens in a very definite type of person. The owner of the migraine tends to be a highly intelligent and conscientious—even over-conscientious—individual (not at all like Mrs. Jones, who says she suffers from it and could by no stretch of the imagination be described either as intelligent or over-conscientious). The headaches are severe, usually on one side of the head only, occur in periodic attacks, and are not, like the headaches suffered by Mrs. Jones, "there all the time." Vision is affected so that there may be hemianopia (*i.e.*, half-vision), flashes of light before the eyes, and the so-called fortification spectra (*i.e.*, zig-zag patterns in the field of vision). The pain is often prostrating, and is usually followed by attacks of vomiting. Migraine is a mystery disease which apparently has something to do with the personality, with emotional stresses, and conceivably in some cases with allergy; the actual pain appears to be caused by spasm of the blood-vessels in the brain. The usual treatment is with tablets of ergotamine (Fermergin), but other remedies are also helpful in different cases.

There are a number of other nervous diseases the cause of which remains a mystery, and of these we shall mention epilepsy, chorea, and pink disease.

Epilepsy is a symptom, not a disease, which is common at all ages but especially children. It has been attributed to St. Paul, Julius Caesar, Napoleon, and (with more justice perhaps) to Dostoievsky. Many varieties of attack occur often in the same patient, the commonest and best known being the *grand mal* or major seizure. In this the patient falls down unconscious and rigid and the jaw is clenched, so that there is danger of the tongue being bitten. This so-called tonic phase is followed, within a minute or so, by a clonic phase in which the limbs contract rhythmically. The attack ends with the patient going limp and gradually recovering consciousness, a process which may take up to an hour. Occasionally the patient has a brief warning, most often an indescribable feeling in the stomach. There are two common forms of minor seizure, one occurring mainly in children and the other more often in adults. The common minor attacks in children are often called *petit mal* or *absence*, which well describes the instantaneous and brief loss of consciousness often unaccompanied by any change in posture. Recovery is equally instantaneous. On the other hand, in the other forms of epilepsy which arise from various parts of the brain, but especially from the lobe under the temporal region, there is often a warning similar to that which may precede a major seizure. In these cases the patient shows only confusion, no definite loss of posture, but automatic activity such as fumbling with buttons, muttering, and grimacing. Following these attacks there may be a quite prolonged period of confusion in which the patient may wander away and occasionally may be violent. Criminal acts are very rarely carried out in this state.

A large number of people have had one or two fits in their lives, particularly at times of physical or psychological stress. "Fever" or "Febrile" convulsions (often called teething fits in the past) are extremely common in young children and are often thought of as something different from epilepsy since the attacks rarely continue in later years. This form of epilepsy and some cases of *petit mal* are the only forms in which hereditary factors are important in the causation, and these are the least serious forms of epilepsy. They are very rarely associated with serious physical or psychological disturbances. Most other forms of epilepsy are due to a scar or other area of brain damage. It is a proportion of these cases which develop the psychological disturbances that are occasionally very serious.

Not every patient who has had one or two fits need necessarily take regular anticonvulsant drugs; that is drugs which damp down the abnormal excessive activity of the brain that leads to the attacks. Many drugs are available of which the most important are phenobarbitone, phenytoin, succinimides, and troxidones, the last two being effective only against minor seizures. Which one to use and whether to use one at all is, of course, quite a complicated judgment, and must be left to the doctor. Epileptics often find difficult to get work because of the reluctance employers to take on someone who may be mo prone to accidents and whose fits may distres other workers. Obviously there are some jo which epileptics should not do because of the dan ger involved, (from, for example, moving machin ery), and they should not drive a car. A fe cases are so severe that work is almost impossibl but employers have a duty whenever possible t employ these people whose mental health ma suffer greatly if they are made to feel outcast and who ordinarily are as efficient, or even mo so, as the next man. It is also hoped tha employees will become less prejudiced abou epilepsy as the general public become less ignorant about medical matters. In this way epileptic will come to be accepted in all those kinds employment for which they are well suited. some of the famous men who have suffered fro this disease had had to rely on the charity of son employers today the world would have been muc the poorer, although possibly we could hav managed without the generals.

The British Epilepsy Association exists give guidance to people with epilepsy, the families, and friends. It provides a full-tim welfare service and a chain of social clubs. It concerned by means of books, films, courses, an lectures to make known the true facts abo epilepsy. It seeks to share its knowledge wi organisations in other countries. Its offices a at 3–6 Alfred Place, London, W.C.1. Te LAN 2704/5.

Chorea, or St. Vitus' Dance, is connected some way with rheumatism, especially wit rheumatic fever. It is much less common tha formerly, and is also known as Sydenham's chore after the English physician who first described and to distinguish it from Huntington's chorea, serious hereditary and incurable degenerati disease which leads to progressive mental deterior tion. Fortunately, Huntington's chorea is rath rare. The patient with Sydenham's chorea is child, most often a girl, and one who has bee rather delicate and nervous. She shows a inability to keep still and makes purposele movements, such as writhing and twitching of th limbs and grimaces of the face. The speech ma be affected, and the muscular inco-ordination ma be so pronounced that dishes or other objects fa from the hands when lifted. The treatment f chorea is that for acute rheumatism with th addition of sedatives. The heart may be affecte

Pink Disease is a disease of young childr between the ages of six months and three yea Why it should be included here is not certain: f its cause is unknown, and the theories to expla its origin range from the supposition that it is vitamin-deficiency disorder, an infection, or th result of poisoning by mercury in teethi powders, to the more probable theory that it is vasomotor disorder like chilblains brought abo by the nerves which control the diameter of th arteries. (Here it should be said that "teethi powders," whether or not they play any part causing this disease, should never be used an how, since in the first place—doubtless to t great indignation of mothers who, of cours always know best—one must say that it extremely uncertain whether the many distur ances allegedly due to teething have anythi to do with teeth at all, and secondly, that wheth or not teething causes anything, it is certain th the numerous powders available in the shops c do nothing about it.) Pink disease was fir described in Australia in 1914, and the gener picture is that of a child in acute misery wi itching or burning of the hands and feet, which a swollen and pink in appearance. Sometimes t face, ears, and nose are affected, there is loss appetite, sweating, insomnia, and thirst. T treatment of the condition, which may last ma months but with an ultimately good outlook, injection of the B vitamins, especially B12, re and sedatives.

Angio-neurotic œdema. Another mysterious disease, common to both children and adults, and mentioned here because it, too, seems to be caused by malfunctioning of the nerves controlling the blood-vessels, is angio-neurotic œdema in which attacks of œdema (swelling) occur in various parts of the body, but are most apparent in the face. Undoubtedly allergy to various foodstuffs can play some part, but emotional factors are at least equally important. Very frequently, without any warning at all—but often after an emotional outburst—the face within a short time swells so that the patient is almost literally unrecognisable. Sometimes the swelling is so severe that breathing is endangered by œdema of the glottis, the entry to the windpipe. An immediate injection of adrenalin usually starts to clear up the condition, and for later use the antihistamine drugs have proved helpful.

THE DEGENERATIVE DISEASES.

There are very many conditions coming into this category, and they are given different names according to the parts of the the nervous system affected. However, they all have this in common, that they are the result of a degeneration of groups of nerve cells, usually for no known reason, and, since nerve cells once destroyed can never regenerate, the diseases are usually irreversible and progressive. In a few cases, however, they can be arrested or simply die out.

It would be impossible to deal even briefly with all these diseases, so here only a few of the more common ones will be discussed. The ones we shall mention are: muscular atrophy, amyotrophic lateral sclerosis, disseminated sclerosis, syringomyelia, and subacute combined degeneration.

Muscular atrophy is, in fact, a whole group of diseases in which there is some damage to the lower parts of the nervous system, usually in the nerve cells at the point where they leave the spinal cord. The common type, *progressive muscular atrophy*, occurs in middle age or over, and the patient begins to note wasting of the muscles in first one hand and then the other. Ultimately, the hand becomes claw-shaped, and some wasting may spread up the forearm. It may finally spread up to the base of the brain, with fatal results. There is no known cure. In children a similar condition is *peroneal muscular atrophy*, in which degeneration of the nerve cells in the spinal cord leads to wasting both of the hands and legs. In this case the disease may stop of itself after several years.

Amyotrophic lateral sclerosis affects both the lower and higher nerve cells. There is wasting of the hands and arms, with increasing weakness, and the legs show a spastic type of paralysis, *i.e.*, they do not waste, but the muscles are in varying degrees of spasm and the knee-jerk and other reflexes are increased. The disease has been treated with concentrated vitamin E, but the results are uncertain. It should be noted that to say that a disease is incurable is not at all the same thing as saying that the patient is going to die from it. Some of these diseases progress very slowly, or may stop of themselves, and any disease process tends to go slower as one gets older. For example, many old people with cancer die of old age long before they are in danger of dying from the disease.

Disseminated sclerosis—sclerosis means hardening of the affected parts of the nervous system—is a progressive condition which goes on with periodic intermissions of improvement. Often the first symptom is double vision or sudden weakness in a limb, but the later symptoms are largely those resulting from loss of muscular co-ordination; thus, when the patient is asked to shut the eyes, stretch out the arm at right-angles to the body and then touch the tip of his nose, he manages the first part of the movement fairly adequately, but as the finger nears the nose it starts to wobble and fails to reach its goal. There is thus some loss of sense of position and difficulty in carrying out such actions as drinking tea from a cup. Another typical symptom is nystagmus, in which, when he is asked to look to one side, the patient's eyes jerk back and forth (this condition is, of course, also a feature of so-called "miner's nystagmus," which appears to have a large psychological element and certainly has nothing to do with disseminated sclerosis). In later stages the spinal cord becomes affected and there are varying degrees of paralysis in the lower half of the body so that the legs are useless and there is loss of control of bladder and bowels. Thus, although disseminated sclerosis is not by itself a fatal disease, it does result in the long run in the patient becoming increasingly bed-ridden. Examination of the nervous system reveals that the covering of the nerve fibres—which have a sort of insulating layer much the same as in the case of electric wires—has been damaged and the underlying fibres have degenerated themselves. Where this damage occurs, and this appears to be completely fortuitous, determines the nature of the symptoms and where they occur. Many treatments have been tried, but their number only emphasises how little we know. The disease may be the result of inborn weakness in the fibres, of allergy, or of a virus infection with a so far undiscovered virus, but since it occurs in young adults in the prime of their life it is a particularly tragic disorder. Strangely enough, it is confined almost entirely to Europeans, and is rare elsewhere in the world.

Syringomyelia, another degenerative disease, is caused by the formation of small cavities in the upper parts of the spinal cord in the neck and chest regions. These cavities become surrounded with scar tissue, and hence interfere with nerve impulses passing down the areas where they occur. The patient may be any age between ten and thirty, and suffers from both sensory and motor symptoms. There is wasting of the muscles of the hand, and sometimes of the arm and shoulder, and specially typical is loss of the sense of pain with retention of the sense of touch. Because of this, the patient may burn or cut his fingers without noticing anything. The disease is slowly progressive over a long period of time, and there is no known effective treatment.

One of the few degenerative diseases which can be treated is *subacute combined degeneration*, which is invariably associated with pernicious anæmia. A middle-aged patient notices numbness, pins and needles, and so-called lightning pains in the fingers and toes and later in the limbs. The muscles are weak, and the tongue is smooth and glossy. On examination, the symptoms of pernicious anæmia are found. Treatment for the anæmia puts a stop to the disease, although damage already done may remain.

INFLAMMATORY DISEASES.

These are those, such as shingles or neuritis, which may be due, as is shingles, to virus infection, or to various causes, as is neuritis. The virus causing *shingles* is apparently the same as that causing chickenpox. Shingles, or to give it its proper title *herpes zoster* (it must not be confused with *herpes labialis* or cold sore of the lips, with which it has no connection whatever), shows itself in the form of a band of pain surrounding the upper abdomen or chest, which is then followed by an eruption with blisters in the affected area. There is no specific treatment; aspirin may be given for the pain and the eruption painted collodion or "New Skin." Ordinarily the condition clears up fairly quickly, but the pain may persist for a long time. Injections of vitamin B12 are sometimes helpful.

The word "neuritis," meaning inflammation of a nerve, covers many different types of illness: polyneuritis, simple neuritis, neuralgia, sciatica, prolapsed vertebral disc, and other conditions. All they have in common is nerve pain; for, as in the case of "colds," one cannot assume that because a condition has one name it represents one disease or has even one cause.

Multiple, peripheral, or polyneuritis is, as the name indicates, a condition in which numerous of the peripheral nerves, mainly in the limbs, are

affected. The symptoms will vary according to whether motor or sensory nerves are attacked. The causes are various: poisons, such as lead, arsenic, or alcohol; bacterial poisons, such as those of diphtheria, typhoid, or gonorrhœa; vitamin deficiencies, as in beri-beri; and, finally diseases of metabolism, such as diabetes. Rarely, an infection known as acute infective polyneuritis causes the symptoms. The parts affected depend to some extent on the cause. Thus alcohol brings about, when taken in excess, pain in the calves and foot-drop (*i.e.*, the foot hangs down and cannot be raised to its normal position); neuritis due to diabetes and arsenic shows similar symptoms, whereas in lead poisoning not only the foot but also the wrist may be affected. Diphtheria tends to attack the palate and the eyes, causing difficulty in swallowing and in vision.

The ordinary type of neuritis, however, is localised—and here it should be said that many pains described as neuritic are nothing of the sort, being probably caused by fibrositis or muscle and joint disorders. Typical of localised neuritis is *Bell's palsy*, neuritis of the facial nerve, in which one side of the face is paralysed so that the eye on the affected side will not shut, and the mouth droops down. Asked to whistle or blow out his cheeks, the patient with facial paralysis is unable to do so. The usual cause of Bell's palsy is cold—for example, it is common to find that the patient has been driving with the car window open in cold weather. But facial paralysis may also be caused by infection in the middle ear. Most cases clear up in a fairly short time, but in a few instances the palsy is permanent. There is very little evidence that the treatments usually employed, such as electrical stimulation, have any effect, but injections of concentrated vitamins B may be used.

Other familiar types of neuritis are *sciatica* and neuritis in the arm. They can be caused by fractures, or pressure from tumours, or the callus (excess bone) in badly healed fractures; cold, too, is said to be a factor, and then there is always "idiopathic neuritis"—which, in everyday language, means that one does not know the cause. Most cases, regrettably, are idiopathic. In sciatica, we have a condition which is not a disease but rather a symptom. The familiar pain down the back of the leg may be caused by alcohol, rheumatism, diabetes, tumour, fibrositis, "slipped disc," arthritis of the hip joint, dislocated sacro-iliac joint, infection such as tonsillitis, and so on. Treatment depends on the cause, which frequently is never found.

Prolapsed Intervertebral disc is a popular disease in these days. It causes a sciatica-like type of pain, and is brought about by the bulging of an intervertebral disc (the shock-absorbers, which lie between the vertebræ of the spinal column) into the area where it can press upon the nerve root. Treatment is first by rest and pain-relieving drugs; if this is not enough laminectomy is performed and the protruding part of the disc removed.

Paralysis agitans or *Parkinson's disease* may result in young adults following an attack of encephalitis, or in older people, in whom the part of the brain concerned simply deteriorates. The face becomes expressionless, the movements stiff and slow, the gait shows a shuffling tendency, in which the patient bends forward and seems to be running to catch up with himself. There is tremor of the fingers and the so-called "pill-rolling" movements, in which the thumb and fingers are constantly moving against each other. Treatment is by drugs, such as hyoscine or more modern proprietary ones; in some cases surgical operation has been used with varying degrees of success. The disease is also known as "shaking palsy."

MENTAL DISEASES.

Psychosis.

Mental diseases are divided into psychoses (*i.e.*, insanity) and neuroses (*i.e.*, what is ordinarily known as "nerves"). Psychoses, in their turn, are divided into organic and functional—those due to physical disease and those in which no physical cause has been discovered. In point of fact, the distinction into organic and functional is rather meaningless; for if we accept the modern view of psychosomatic medicine which regards the body and mind as a single unit it is clear that organic disease brings out psychological defects which were already there and that functional disease must, in the final analysis, be the result of physico-chemical causes, even if this is brought about by mental stress.

Organic disease results from poisoning of the nervous system by such poisons as alcohol, carbon monoxide, or lead; vitamin deficiencies, as in pellagra; infections such as syphilis; and degeneration of the brain, either primary or as a result of poor blood supply. In all cases its main symptoms are confusion, signs of other disease, and loss of memory. Alcohol leads to various conditions: in *delirium tremens* heavy bouts of drinking end in delirium ("D.T.s"), confusion, hallucination—although not necessarily of pink elephants or rats. It is a serious disease, but the outlook is much improved since it was discovered that injections of concentrated vitamins B and C in the form of "Parentrovite" can help. In more chronic cases *Korsakov's syndrome* manifests itself in the form of mental deterioration and memory defects. There can be little doubt that previously existing mental instability is a predisposing factor in these conditions. The same may be said of *general paralysis of the insane* or G.P.I., and in this case the immediate cause is syphilitic infection of the nervous system. Nevertheless, of all the patients with chronic syphilis, only a small number get syphilis of the nervous system. G.P.I. is typically associated with the usual symptoms of organic disease and delusions of grandeur; for example, a man with this disease may go out and buy several expensive cars in one day. However, it is not uncommon to find G.P.I. associated with severe depression—again the picture depends on the previous personality. At one time G.P.I. was considered hopeless, but treatment by malaria (that is, deliberate injection of malarial germs) was found to be helpful. Today, although in some places the treatment is still used, penicillin is found to be adequate. The association of the above symptoms with a positive Wasserman test—which proves the presence of the spirochæte in the blood—indicates neurosyphilis. When the lower centres of the nervous system are affected the disease is known as *tabes dorsalis*, in which there is difficulty in passing urine, limb pains, inability to stand when the eyes are closed, and finally difficulty in walking. The patient becomes paralysed and ultimately bedridden. Treatment is with penicillin.

People age at varying rates, so that some are hale and hearty at eighty or ninety whereas others are old at sixty or seventy. They present the typical picture of old age: "second childishness and mere oblivion, sans eyes, sans teeth, sans everything." When this condition, which is caused by degenerative changes in the brain or by defective blood-supply resulting from arterio-sclerosis, is pronounced we speak of *senile psychosis*. There is mental confusion, forgetfulness, and delusions, in which the previous personality defects which we all have are accentuated. Such patients may have to be put under special care, but the process is largely irreversible.

The functional psychoses are two in number: schizophrenia and manic-depressive insanity. In *schizophrenia*, which, when it occurs in early adult life, is known (or used to be known) as *dementia præcox*, the symptoms are bizarre. There are delusions and hallucinations, so that the patient often believes himself to be persecuted and hears voices which say objectionable things to him. Sometimes the schizophrenic is wildly excited, and in other cases he goes into a state of stupor which is described as a catatonic state. Although the disease is described as functional recent discoveries seem to suggest that there is some derangement of the blood chemistry. Treatment by insulin and the new tranquillising drugs has revolutionised the outlook in this admittedly serious disease. Indeed, some cases of psychosis are more easily treated than neurotic patients, since the former respond to physical

methods, whereas the latter may require fairly prolonged psychotherapy (psychological treatment) and are less responsive to drugs.

In cases which do not respond to other methods, the brain operation known as *leucotomy* may be performed. Leucotomy is also performed to alleviate intractable pain, as in incurable cancer, but some of the ataraxic drugs (tranquillisers) are probably equally useful for this purpose. Leucotomy involves the severing of the connecting nerve fibres between certain areas of the brain, and the results are often favourable, but in fact the operation should be performed only in cases where the outlook is otherwise very poor; chronic severe neuroses, frequent attacks of manic depressive psychosis, severe chronic depression, and schizophrenia which has not responded to other forms of treatment. The operation reduces anxiety, fear, aggressiveness, and agitation, but may result in the less-desirable symptoms of apathy, impaired judgment, lack of self-control, and loss of initiative.

Schizophrenia developing in later life is likely to be less dramatic in origin, and the delusions tend to be more systematised—that is, they take a persistent form, which does not change from day to day. This type of the disease is known as *paraphrenia*. In those beyond middle age the rare but dangerous condition described as *paranoia* may develop in which there are no hallucinations and the only symptom is a completely systematised collection of persecutory delusions, which on recital may sound entirely convincing even to the ordinary doctor. Such people are dangerous precisely because they are so plausible, and they fill the ranks of the litigious, the troublemakers, and the political and religious eccentrics. One such patient known to the writer spent his life in a mental hospital from which he had parole, employing this to form a society propagating highly eccentric sexual and political beliefs. It says little for the intelligence of the general population that his meetings were invariably crowded out (although, of course, when one reads of the people who apparently believe that the various fictitious families on radio or television—the Groves, the Archers, and the like—really exist, one need not be surprised at such examples of communal dottiness, even if one may despair of democracy).

Manic-depressive insanity is characterised by mood swings in which the emotions alternate between wild elation without obvious cause and equally causeless depression. However, the picture is not quite as simple as this; for phases of mania or excitement may occur without depression obviously following, or there may be a single attack of depression with no manic phases. The disease may be absolutely incapacitating, or there may be periods of relative normality; typically, then, manic-depressive insanity is a disease of alternating moods. The depression responds to electroconvulsive therapy or E.C.T., but mania is less responsive to treatment. However, it ordinarily remits of itself. Sometimes in middle age *involutional depression* occurs, and this in the vast majority of cases is cured by E.C.T. As in the case of schizophrenia drugs are increasingly used for depression. Chlorpromazine in the former case and in depression Nardil or Tofranil, etc. The ever-present risk in depression is suicide.

Neurosis.

The main neuroses are anxiety neurosis, hysteria, and obsessional neurosis. *Anxiety neurosis* is an illness in which the main symptom (as the name implies) is anxiety. There is fear which rationally the patient knows to be groundless; there may be anxiety attacks, in which the heart pounds, the patient feels he is going mad, is unable to sleep, and worries "for no reason at all." In hysteria, anxiety is largely absent, but there may be apparently physical symptoms ranging from paralysis of the limbs to blindness, deafness, inability to write, and lapses of memory (the so-called hysterical fugues or loss of men ory). Typical of *hysteria* is the fact that the patient is less worried by his symptoms than would be expected from their apparent seriousness; this is what the early psychiatrists described as "la belle indifférence." The reason for the indifference is simple—it is that the paralysed individual *wants* to be paralysed, the blind *want* to be blind, the deaf to be deaf (there are none so blind—or deaf—as those who don't want to see, or hear), and the person who doesn't want to write conveniently finds that he cannot.

Generally speaking, neurotic people are suffering from a failure to face up to reality. They are not physically ill and are largely the end result of a faulty upbringing. It is wrong to suppose that the only bad families are those in which the children are ill-treated; much the worst ones are those in which children are spoilt, the parents possessive, and the wrong kind of love is dispensed. Neuroses are the result of a conflict between primitive desires and what the individual has been brought up to believe he should be. For example, before an examination a student may develop a nervous breakdown because he fears failure when he has been brought up to expect success. The excuse, of course, is "overwork"—an entirely non-existent condition. With his breakdown he solves his problem, he avoids the fear of failing and preserves his self-respect: he has been ill. Similarly, the soldier with "shell shock" (another non-existent condition) has a conflict between his sense of duty and his fear of death, which again is solved by becoming ill. Or, to take a final example, a woman feels the duty to look after her ageing mother. But she also wants to get married. So she unconsciously develops a neurosis which says, in effect, "I should like to do my duty by looking after my mother, but unfortunately I am unable to." There is an unconscious rebellion on the part of the mind.

Neurosis, in effect, is not a disease—it is a self-inflicted injury, a form of maladaptation to life. The neurotic, no matter how much he suffers, does not want to get well; he has found some way of getting along, even if a foolish way, and he intends to keep it. Often his symptoms are the sort of excuse that say: "If only I wasn't ill what wouldn't I be able to do!" The neurotic is a person who is different and is afraid to be himself; his problem is a conflict between being "ordinary," "like other people," and being what he was supposed to be. You will find some further references to neurosis in Section Q, Part II.

Obsessional Neurosis is a more severe type of neurotic illness; for although in anxiety neurosis we find such symptoms as phobias—irrational fears of open spaces, closed spaces, animals, and so on—obsessional states are characterised by compulsive feelings that certain acts must be performed or certain thoughts thought. In a mild form we all have obsessions: we feel that we must walk on the spaces between paving-stones, that we must touch lamp-posts, and so on. But when this type of compulsion gets to the stage when we must go back several times to make sure the lights have been put out, when we feel the need to wash our hands every few minutes, become obsessed with numbers on cars or dates on coins, then it becomes a nuisance and requires treatment. Usually the treatment is psychotherapy—whether psychoanalysis according to the method of Freud or shorter methods—and, in serious cases, physical methods such as L.S.D. (lysergic acid) or leucotomy. The obsessional neurotic is a person who feels that life must be controlled; he is "a creature who moves in predestinate grooves—he's not even a bus but a tram." His symptoms are an attempt to devise self-imposed rules which will control the unconscious desires of which he is so afraid.

Neurasthenia is an entirely imaginary condition allegedly due to exhaustion of the nervous system. Since no such condition exists, we need not bother with it. Neuroses cannot be treated by feeding the nerves (which are perfectly normal). They can be helped by such things as sedatives, but not cured. *Neurosis has nothing at all to do with disease of the physical nerves, so nerve tonics do not*

exist, and anyone who asserts that they do is a humbug. Glycerophosphates and the usual contents of tonics are excreted almost as soon as they are taken in, and tonic wines are one of the best ways of becoming an alcoholic. The one reason for not taking alcohol is when one craves it, and many a "respectable" old lady has required several dust-carts to carry away the store of empty bottles left behind when she died.

Psychopathic Personality is the term given to anyone who has different standards of behaviour from those generally accepted by society. Some of these unfortunates may be *inadequate*, that is to say, although perfectly intelligent, unable to earn their own living. Others are the *creative* people, who, as in the case of Van Gogh, did many eccentric things but also many productive things—Van Gogh was gifted, or cursed, with an intense sensitivity. Lastly, there are those who have what others regard as peculiar sexual habits. Of the first two classes nothing more need be said, and all that is necessary is to mention certain of the so-called sexual perversions. (When we say so called the implication is not that none of these forms of behaviour is perverse but that some of them are carried out by otherwise quite ordinary people.) *Sadism* and *Masochism* refer to, in the first place, pleasure in inflicting pain and, in the second, to receiving pain. The pleasure is sexual, and it is incorrect to talk of cruelty in itself as sadism. Sadism is named after the Marquis de Sade, who suffered from this perversion, although he certainly did much less harm in his small way than numerous politicians or generals of our time, and masochism is named after the Austrian novelist Sacher-Masoch, who wrote books which, although unpleasant, were not notably more so than certain Sunday newspapers of today.

Masturbation is sexual self-stimulation. Needless to say, it produces no more *physical* harm than ordinary sexual intercourse—that is to say, none at all, although some people have the strange belief that every act of intercourse weakens the body and it has even been believed that each act shortens life by a specific length of time. This is rather illogical in view of the fact that most of the famous rakes have been noted for their longevity! Masturbation is almost universal in infancy, adolescence, or even in later life when other outlets are not available. It need only be a matter of concern: (*a*) when it is chosen in preference to normal sexual activity, or (*b*) when it is compulsive and excessive, since then it is a sign, not of sexual desire, but of severe underlying anxiety.

Homosexuality is, as presumably most people now know, an attraction between individuals of the same sex. Feminine homosexuality is not illegal in Britain, but male homosexuality is. The Wolfenden Report of 1957 takes a much more tolerant view of the problem than has been hitherto current, recommending, in effect, that homosexual acts between consenting adults should be legalised. Homosexuality is, so far as is known, not inherited, and is the result of psychological difficulties in early development; occasionally it can be treated by psychotherapy, but it is doubtful whether those "cured" in this way were ever genuine homosexuals. To any humane person it must seem that the Wolfenden Report gives a sensible solution to the problem; for it is difficult to see why the homosexual should be treated differently from the heterosexual offender. That is to say, what adults do (with consent) together is their own business, but the male homosexual who seduces a boy under age should be treated in no way differently from the man who seduces an under-age girl.

All that remains to be said is that many of these conditions are treatable or, if not treatable so far as cure is concerned, they can at least be relieved. The world is full of people who are "different": there are those who are different in the right way, who should take satisfaction from their achievements, and those who are different in the wrong way, who should seek expert advice. Since psychological treatment is time-consuming, it is not very easy to obtain it within the National Health Service, although group treatment has simplified the problem. However, any person with such difficulties would probably benefit from a discussion with his family doctor.

DISEASES OF THE SKIN.

The skin in the course of development before birth is particularly closely associated with the nervous system. It is therefore not surprising that so many skin diseases are influenced by emotional states. Other causes of skin diseases are infections, glandular disorders, vitamin deficiencies, and the numerous conditions for which no cause has been discovered, but which presumably are due to metabolic disorders.

One of the commonest skin symptoms is *itching or pruritus*. It may accompany many different general diseases, for example diabetes and jaundice. It may also be troublesome during the menopause (the change of life in women), in old age, or in nervous conditions. Sedatives and sex hormones sometimes help the itching during the menopause, and there are ointments which may be useful.

Itching in the region of the anus and genital organs is relatively common. It may be caused by worms, by irritating vaginal discharge, or by sugar in the urine, as in diabetes. The alteration in the normal bacteria of the bowel which follows treatment with various antibiotics also often causes anal pruritus and soreness. In many cases however the itching has some psychological cause. In treatment it is important to avoid ointments and creams which contain a local anæsthetic because these substances can cause severe allergic reactions if used for longer than a few days, and may thus make the condition much worse. Treatment with a local corticosteroid application is more effective and safer.

Parasites, such as the *scabies* mite or *lice* can cause severe and persistent itching. The scabies mite is very small, and since it burrows under the skin surface, is unlikely to be seen; it is the cause of itching most commonly between the fingers and on the front of the wrists. The itching is worst when the body becomes heated, as in bed. Treatment consists of painting the body from head to foot with benzyl benzoate application, followed the next day by a hot bath. Since scabies is contracted through close personal contact with an infested person it is often desirable for several or all members of a family to be treated at the same time, even though only one of them may be affected. Lice are specialists, one type of which affects the scalp, another the body, and a third the genital area. Head lice are destroyed by lethane, body lice by D.D.T (dicophane) powder and genital (pubic) lice by shaving off hair and washing. Obviously, the clothes, especially in the case of body lice, should be disinfested, either by the use of D.D.T. or, if this is not available, by using a hot iron over the seams, which lice (for some inexplicable reason) seem to favour. Apart from the discomfort they cause, lice are dangerous as potential carriers of typhus fever.

Baldness, or Alopecia, is a very common condition, as is manifested by the extraordinary number of preparations advertised as curing it. When many preparations are offered for the treatment of one condition it is a fair judgment to assume that none of them is likely to be effective. There are, in fact, two types of baldness; one, which is much the commoner, is hereditary, and cannot be influenced in the slightest by any treatment, the other, *alopecia areata*, is caused by nervous stress and would recover in most cases by itself, whether one used a solution of soot and water or the most expensive "hair food." There is no such thing as a hair food, any more than there is such thing as a nerve food, and although it is probable that hair hygiene may delay baldness, it certainly cannot prevent it. All hair tonics and "foods" are useless, and their uselessness is only equalled by their costliness. Those who have lost their hair and find it growing again after using some alleged tonic are people who have had *alopecia*

creata and whose hair would have grown back anyhow. In women the hair often thins out soon after a pregnancy, but a few months later it usually returns to normal.

Seborrhœa is a condition in which there is over-activity of the sebaceous glands. The most usual form it takes is *dandruff*. However, it takes other forms, and those who have dandruff may also have rashes on the face, shoulders, and chest. In these areas there is a patchy, greasy, and often itchy, rash which does not clear up until the primary condition in the scalp is dealt with. The scalp should be washed with one of the modern sulphur-containing shampoos at least twice a week, and the affected parts on the face and chest can be dealt with by the use of a sulphur lotion (*not* on any account by greasy ointments). Seborrhœa is not in itself difficult to treat, but, since the condition depends on over-secretion of sebum, the skin lubricant, treatment may have to be persisted in during the years of early adulthood, when it is most active.

Erythema Intertrigo is, quite simply, the sort of irritation which occurs usually from excessive sweating under the armpits, between the legs, and under the breasts in women. All that need be done is to wash frequently and to dust the affected areas after washing with powder. This is the condition which, in the tropics, is known as "prickly heat" and elsewhere as a "sweat rash." In some people *hyperidrosis* or *excessive sweating* is a problem, especially when the sweating is accompanied with body odour—the sort of thing that, according to the advertisements, "even your best friends won't tell you." There is little need for anyone in these days to suffer in this way: for the cosmetic firms have produced many highly efficient deodorants which not only control odour but also control the amount of sweating. Chlorophyll, which has been much advertised as removing odours, is effective when applied directly to surfaces which give off an unpleasant smell. It is however ineffective when taken by mouth, and does not prevent body odours. Stale sweat smells bad because it is decomposed by bacteria, and this type of body odour can be largely prevented by preparations containing a harmless antiseptic such as hexachlorophane and an anti-perspirant such as aluminium chloride (see *Which*, February 1960).

Erysipelas is an infection of the skin caused by the hæmolytic streptococcus. It begins as a red, raised area anywhere on the body where the germs have been able to enter through a small crack or cut in the skin. The red area advances and spreads over the body until the disease is got under control. Erysipelas is very infectious, and those who look after the patient should wash their hands throughly after contact. At one time the disease used to spread as an epidemic throughout the hospital wards, but this is very rare nowadays. Treatment is, of course, a matter for the doctor.

Chilblains are common in cold weather, especially in those with poor circulation. Ordinarily they occur in the toes and fingers, but may appear on the nose and ears. The part affected becomes swollen, dusky, and there is pain and itching, sometimes leading to ulceration. Protection of the body, especially the hands and feet, from cold is the best and the only really effective way of preventing chilblains. Warm lined gloves and footwear, and warm stockings or trousers should be worn outdoors. Adequate heating of rooms is essential: a temperature between 18° and 21°C is recommended (65°–78°F). Most tablets, medicines, ointments, or creams for chilblains are useless. A skin affection caused by heat is rather grandiosely described as *erythema ab igne*, and is frequently seen on the legs of ladies addicted to roasting their legs before the fire. It takes the form of red patches on the front of the legs, and can be removed only by avoiding the cause.

Dermatitis means "inflammation of the skin," and therefore the word could be, strictly speaking, applied to any skin disease. In fact the term is used almost interchangeably with the term *eczema*. There are three main types of dermatitis or eczema. The first, *primary irritant dermatitis* results from injury of the skin by some powerful chemical, such as strong alkali or turpentine. The second, *contact dermatitis* is due to sensitisation of the skin to some substance which is normally liable to cause this type of allergic sensitivity; examples are nickel (in jewellery and suspender buckles), epoxy resins, rubber additives, primulae and chrysanthemums, and even ingredients of cosmetics. Contact dermatitis may continue for a long time, even after the patient is no longer in contact with the offending material. The third type is often called *constitutional eczema*. Although the skin is apt to react adversely to various irritants and sensitisers the major part is played by the personality, and there is often a history of eczema, hay fever or asthma in the family. Treatment is more difficult, but local corticosteroids and tar, sedatives and psychological treatment can be of great help. Infantile eczema also belongs in this category, but in most patients it disappears as the child grows up.

Impetigo is an infectious skin disease caused primarily by the streptococcus, but later often infected with staphylococci. It usually occurs on the face, and takes the form of blisters filled with pus on a red base; when the blisters burst their place is taken by yellow crusts. Impetigo is very infectious and easily spread by the fingers, dirty towels, or cloths; therefore, one of the first necessities is to prevent infection of others or reinfection of oneself by avoiding scratching and using a different towel each day, which must on no account be used by anyone else. Treatment is simple with an antibacterial ointment, so the main issue is prevention of contamination.

Sycosis or "Barber's Rash" occurs in men, and is similarly treated.

Urticaria or *Nettlerash* is a familiar skin disease in which itching weals appear on the skin, usually for no obvious reason. It is not infectious, and can be caused by nervous stress, certain drugs, allergy to some foods, or even exposure of the skin to cold. In some people it is possible to write on the skin with a fingernail: the "writing" appears in the form of weals. This is known as *dermographism*; it occurs in many normal persons as well as in many patients with urticaria. The antihistamine drugs are the most useful in the treatment of urticaria. Urticarial swelling of the tongue or throat must however be relieved at once and is treated by an injection of adrenaline.

Acne, or "*Blackheads*," is a condition found on the face and shoulders; its appearance is so familiar that no description is necessary. Acne is one of those conditions which is the end result of many factors. There is, first, a greasy skin, the result of glandular upset (which is why the disease usually occurs in adolescence); secondly, there is infection of the skin; and thirdly, there is blockage of the sebaceous ducts, which ordinarily allow the grease from the skin to pass out on to the surface. Since the condition starts with excess secretion of grease, ointments should never be used, and probably the best applications are drying lotions containing some sulphur preparation which inhibits secretion of grease. The face should be frequently washed, and it is possible now to obtain detergent solutions which are both antiseptic and prevent grease formation. In severe cases ultraviolet ray treatment may be necessary.

Rosacea. As has already been implied elsewhere, although the wages of sin may be extremely unpleasant, the wages of extreme virtue may be no less troublesome. Thus *rosacea*, in which the nose and cheeks become red and greasy and the skin coarsened, occurs alike in chronic alcoholics and elderly ladies with no vices other than a preference for strong tea. Both cases are associated with indigestion, since, regrettable as it may seem, strong tea and alcohol are about equally liable to cause the gastritis which may be at the root of this complaint. However, in many

patients the chronic flushing is caused in other ways and psychological factors are important.

Lichen Planus is one of the numerous skin diseases which seem to be due to nervous states of tension. It may occur on any part of the body, but is most common on the front of the forearms and legs. The rash takes the form of nodules which are lilac in colour and have a dent on the top; when these disappear a stain is left behind. There is severe itching. Treatment is a matter for a doctor, as it also is in the case of *psoriasis*, a very common disease of largely unknown origin, which is extremely resistant to treatment. It tends to run in families. It takes the form of slightly raised papules, usually on the elbows and knees; typically the papules are covered with dry, silvery-looking scales. Apart from the rash, the patient is usually in perfectly good health and there is no itching. Many drugs have been used in psoriasis, notably chrysarobin, and while it is not difficult to cause the rash (which may occur anywhere on the body) to disappear in one area or even in all areas for a time it has a strong tendency to return.

Warts, or *Verrucae* are familiar enough. They are caused by a virus, and are, theoretically at least, contagious (although having removed many warts, the writer has never found them contagious). Most frequently they are found on the hands, but may occur elsewhere. Treatment is best carried out by a doctor, who will use a cautery, a caustic carbon dioxide frozen into "snow". A curious feature of the common wart is that it can sometimes be caused to disappear by suggestion, which is presumably why so many old wives charms are not necessarily without effect. Different altogether from the common wart is the *plantar wart*, which occurs on the soles of the feet and often causes a good deal of discomfort. It is best dealt with by a chiropodist or in bad cases by a skin specialist since it is highly infectious.

Ichthyosis is a disorder of horn formation with which some unfortunate people are born. The oil and sweat-producing glands do not function well and the skin is dry and scaly like the skin of a fish. It is, however, possible to help the condition, which does not affect the general health, by frequent alkaline baths to wash off the scales, and the subsequent use of lanolin to replace the lacking oil. Large doses of vitamin A seem to help in some cases, and there have been reports in the medical Press of cases being helped by hypnosis; this, however, is very much a matter for speculation.

Cancer, Rodent Ulcer, and Cysts. Cancer of the skin occurs mostly in old people, and takes the form of what is described as an *epithelioma*. It is most common on the face or hands, and usually appears as a nodule which breaks down and produces an ulcer. The glands may later be affected, but such cancers can almost invariably be cured unless a considerable time has elapsed during which they have been neglected. *Rodent ulcer* is a form of ulcer which appears on the inner corner of the eye or the side of the nose in old people. It does not spread over the body, but acts by eating into the tissues in the area where it has started. X-ray or operation is necessary, but the outlook is good. *Cysts* on the skin are due to blockage of the sebaceous glands. They may become very large, and are best removed, as they may become infected. They do not turn into cancer, and there is no such thing as "male" and "female" cysts. It does sometimes happen that *moles*, especially of the bluish-black type, may become malignant, so it is perhaps best to have them removed surgically when they exist. *All moles which change in appearance or size should be at once referred to a doctor.*

Skin Grafts.

These are a very complex subject which can be only briefly discussed here. They are used basically for a number of conditions in which large areas of skin have been removed from the body, as in burns or serious accidents. In other cases, as in plastic surgery, grafts may be used to make a new nose, eyelids, and so on. The following are the main types:

Pinch Grafts are small, circular pieces of skin cut from some other part of the body. (The former method of using grafts from another person has been given up almost completely, since such grafts—except in the case of identical twins—never "take.") The small pieces are laid on the area without skin and gradually grow together.

Split-thickness grafts are grafts removed from another part of the body by an instrument known as a dermatome, which cuts sections about 4 in. by 8 in. containing part of the deep layers of the skin.

In *Full-thickness Grafts*, on the other hand, the whole thickness of the skin is removed from elsewhere and applied to an area which has to bear friction or heavy weights, such as the hand or the foot. Lastly, and this is largely used in plastic surgery, there is the *Pedicle graft*, which, unfortunately, although it is certainly the most exciting type, is rather difficult to describe. Briefly, if one, for example, wants to make a new nose, one cuts an area of skin and underlying fat about 2 in. wide and 5 or 6 in. long in the abdomen. One end, however, remains attached so that it gets adequate blood-supply. The problem is how to get this tissue to the nose, and this is done by a complicated process of leap-frog. First, the free end of the graft is attached to the forearm, whilst its "root" remains in the original site, and when it begins to grow and get its blood supply from the arm, the original "root" is cut. So we now have a "sausage" of tissue attached to the arm. The arm is then lifted to the face and kept firmly in position there until the new free part becomes attached. It is then detached from the arm, modelled to the correct shape, and grows where the nose used to be!

THE RHEUMATIC DISEASES.

The main rheumatic diseases (or so they are described, although they seem to have little relationship one with the other), are *rheumatic fever*, the acute form, which has already been dealt with (P28); *chorea*, or rheumatism of the nervous system, also mentioned (P49); *rheumatoid arthritis*; *osteoarthritis*; and *gout*. The only thing these diseases seem to have in common is that most seem to be associated with the connective tissues, muscles or joints—this, of course, with the single exception of chorea. Apart from this there is very little similarity.

Rheumatoid arthritis often starts without evident cause in early adult life, and affects the small joints of the fingers and toes, causing swelling and pain. No infective process has been discovered, yet the disease goes on and on, sometimes better, sometimes worse. It is (and this is all one can say) a disease commoner in women, commoner in temperate climates, commoner following emotional stress. Although, as we have seen, rheumatoid arthritis is a disease characterised by frequent remissions, it takes a considerable time to burn itself out. The most likely explanation for its occurrence is that stress reactions act on the suprarenal glands and the secretion of cortisone is inadequate to play its usual part in preventing the body from responding too severely to injury. However, the injection of cortisone has proved, on the whole, less useful than might have been expected, and there is little reason to suppose that in most cases it is any better than aspirin.

Osteoarthritis is essentially a degenerative disease of old people. The bones affected are ordinarily the larger joints: the shoulders, the hips, or the spine. There is no disease in the ordinary sense, and essentially what has happened is that these joints have got "old" and the bone has overgrown so that movement is less simple than it once was. Osteoarthritis is not curable, but can be relieved by drugs and physiotherapy.

Gout, so far as one knows, has nothing at all to do with rheumatism. It is a metabolic disease caused by the inability of the body to deal with certain protein breakdown substances, such as uric acid. Typically, the pain develops in the big toe, and the foods concerned are such luscious products as wines, spirits, liver, sweetbreads. Although drugs such as cinchophen can help, the plain fact is that those liable to gout cannot have sweetbreads and wine, liver and spirits, without having gout as well. Most people, perhaps, would prefer the food and wine, but those who dislike gout must abstain.

DISEASES OF THE EYE.

The Eye.

The eye is frequently compared to a camera, and in a general sort of way there is some resemblance. The eyeball consists of 3 coats within which are contained the refraction media: (1) The outermost layer, the main support of the eyeball, comprising the sclera (opaque) and the cornea (transparent, covering the front of the eyeball). The conjunctiva (the part which gets inflamed when you get germs or dust on the surface of the eye) is a thin protective membrane covering the sclera and doubles back to line the inside of the upper and lower lids. It stops at the junction of the sclera and cornea. (2) The middle layer containing many blood vessels which forms the choroid and, in front, the iris (the coloured part of the eye). The muscle in the iris enables its central aperture, the pupil, to contract in bright light, and to dilate in dim light. (3) The innermost layer of nervous tissue, the retina. The retina contains the expanded termination of the optic nerve which is part of the brain. Behind the iris is the lens, which is controlled by a series of muscles which increase or diminish its curvature, and thus produce, according to the nearness or distance of the object, a clear picture on the retina. Some of these parts may, of course, be affected by disease. Here we shall deal only with a few of the more common diseases.

Blepharitis is an infection of the eyelids which is easily recognisable from the red, sore appearance at the margins, the formation of crusts, and the falling-out of the eyelashes. If it has just developed, an attempt may be made to treat it at home with hot bathing and the so-called Golden Eye Ointment, but *blepharitis* is liable to become a chronic disease, and it is wiser to see a doctor. Penicillin cream or ointment can cure the disease, but must *never* be used save under medical advice; allergy to penicillin is commoner in the eyes than anywhere else, and in some cases patients have lost their sight through its use in this way.

Conjunctivitis is the result of infection of the conjunctiva, and the symptoms are the familiar ones of a feeling as if some grit had got into the eye, running from the eye, and frequently gummed-together eyelids in the morning. In some cases it can be treated by hot bathing and eye-baths with one of the proprietary lotions on the market, but it is much wiser to see your doctor, who can supply much more effective remedies and may save you a lot of unnecessary discomfort.

Other Eye Diseases. We can only mention briefly *keratis*, inflammation of the cornea; *iritis*, inflammation of the iris; and *glaucoma*. These are all potentially serious diseases, and should not be diagnosed or treated by the layman. Glaucoma, in particular, may lead to blindness if help is not sought in time. If there is redness and congestion over the eye, dimness of vision, *severe* pain (as contrasted with the irritation caused by conjunctivitis), and perhaps even vomiting, the doctor must be called immediately.

The main disease of the lens is *cataract*, in which the lens becomes opaque and varying degrees of blindness result. Ordinarily, cataract is a condition found in people after middle age, but sometimes it is found in children at birth. The treatment is by operation—one which has been carried out for centuries—in which the opaque lens is removed. The patient thereafter has to wear glasses, but the vast majority of patients obtain good vision.

In *retinitis*, however, where the "screen" at the back of the eye is affected, the general outlook is more serious. This is because, whereas cataract is a localised disease, retinitis often signifies some bodily illness: infection, hardening of the arteries leading to hemorrhage, diabetes, or kidney disorders. Sometimes the retina becomes detached, leading to blindness. As has been suggested above, except in very minor conditions such as styes (a localised infection treated in the same way as blepharitis), or conjunctivitis, the doctor should always be consulted. He should be consulted, too, when a foreign body gets into the eye unless it can be removed by very gentle manipulation with a handkerchief, for it must be remembered that such "poking about" on the surface of the eye may do much more harm than the original condition. So, if a couple of minutes fail to remove the grit, give up, and go to the surgery.

DISEASES OF WOMEN.

The *internal sexual organs* of a woman, like the urinary system, can best be described as shaped like a capital Y. At the tips of the arms of the Y are the female sex glands, the ovaries: the two arms running downwards are the Fallopian tubes: the point where the arms meet is the womb or uterus: the single leg of the Y is the vagina. These are the *primary sexual organs* of a woman and they undergo regular cyclical changes in response to the control exercised over them by the pituitary gland, situated in the base of the skull. This control is mediated by chemical messengers (hormones) secreted into the circulation. The ovaries also secrete hormones, oestrogen, and progesterone, and a delicate hormonal balance is maintained between the pituitary gland and the ovaries. Each month an egg cell (ovum) matures and is released from the ovary, usually midway between two menstrual periods: the ovum is wafted along the Fallopian tubes by waves of contraction and if fertilised embeds in the lining of the uterus which has been conditioned to nourish it by the ovarian hormones. If it is not fertilised the ovum escapes from the uterus, altered hormone levels then cause the lining of the uterus to be shed (this is menstruation), usually about 14 days after ovulation. After menstruation a new cycle begins: another ovum matures and a fresh lining grows in the uterus. These cyclical changes recur from puberty to the menopause. Menstruation does not occur during pregnancy, of which a missed period is often the first sign. However, women do miss periods even though they are not pregnant, and this usually means that some minor and temporary change has occurred in the hormone balance. If three consecutive periods are missed it is wise to consult a doctor.

The *breasts* are called *secondary sexual organs* and are also under the influence of the ovarian hormones. Women are sometimes worried because they believe that their breasts are either too small or too large. However, small breasts cannot be made larger and are just as efficient for feeding babies as large ones, which are not always as effective as they appear. If breasts become too large they can be dealt with by plastic surgery. Two conditions which do need treatment are *mastitis* and *cancer of the breast*, both of which are characterised by lumps within the breast tissue. Mastitis may be uncomfortable but is not dangerous and can be treated medically, whereas cancer is more serious. The distinction between mastitis and cancer can only be made by a doctor and any woman who discovers a lump in her breast must seek medical aid *at once*.

Abscesses also occur in the breast, nearly always when the mother is feeding her child. Here again, a lump appears, the breast becomes red and very tender, and the woman may be feverish.

Treatment with antibiotics is sometimes successful, especially if the mother consults her doctor quickly, otherwise treatment is by a small operation.

The Ovaries. The two commonest diseases of the ovaries are cysts and disorders arising from hormonal imbalance. The symptoms of ovarian disease are usually abdominal or low back pains, and heavy and painful loss during the periods, which may become irregular. These signs should be taken as a warning to consult a doctor.

The Fallopian Tubes. Infection of the Fallopian tubes is called salpingitis. The membrane lining the tubes is continuous with the lining of the uterus, hence an infection is rarely confined to a circumscribed area in either the tubes or the uterus, and pelvic inflammatory disease is a better name for this condition. Pelvic inflammatory disease often follows an abortion, or childbirth where part of the afterbirth (placenta) has been retained, or can spread from an infection in a nearby organ, for example the appendix. Infection is sometimes conveyed by the blood from another septic source in the body. The gonococcus is another cause of infection. The disease is characterised by pain and tenderness in the lower part of the abdomen, accompanied by fever general malaise and frequently (but not invariably) a vaginal discharge. The treatment of pelvic inflammatory disease is usually medical and is the same irrespective of the primary site of infection. Before the introduction of antibiotics the disease often became chronic and the Fallopian tubes were frequently blocked by a cicatrising scar, a cause of subsequent sterility.

The Uterus. This is a hollow muscular organ and both its musculature and its lining membrane can be the site of disease. *Fibroids* are non-malignant muscular tumours which develop in many women. The main symptom is a heavy menstrual loss and surgical removal of the uterus (hysterectomy) is often necessary. This is a major operation, but modern anæsthesia and operative techniques minimise the discomfort. Hysterectomy does not impair sexual pleasure, but no more babies can be conceived. Infection of the lining of the uterus is usually part of a generalised pelvic inflammatory disease (*see* Fallopian tubes).

Cancer of the Uterus and Cervical Smears. The uterus is pear-shaped and consists of a body and neck. The wide end is uppermost (the body) and the narrow neck (cervix) projects into the top of the vagina. Cancer of the cervix is commonest in middle-aged women who have married young and have had a large family; cancer of the body of the uterus usually occurs after the menopause and is most common in childless women. The symptoms are variable and it is sufficient to emphasise that any woman who has unexpected bleeding, especially after intercourse, whether her periods have stopped or not, *must* see her doctor at once. The treatment depends on individual circumstances, but is usually by operation. It is now possible to detect cancer of cervix long before symptoms develop and at a stage when the disease can be eradicated by a relatively small operation. This early detection has been made possible by the development of exfoliative cytology. Cells taken from the cervix (without discomfort to the woman) are examined under a microscope. This test is popularly known as the "cancer test" or "cervical smear." A cervical smear is often taken as part of the routine gynæcological examination by consultants, general practitioners, and family planning doctors, and is also being included in some population screening programmes. It is a big step forward in preventive medicine and may ultimately solve the problem of cancer of the cervix. Every woman between the ages of 25 and 60 should seize any chance to have this test done.

Prolapse means a sagging down of the uterus into the vagina and the cervix may even appear at the outside. It is a result of frequent childbirth and laxness of the ligaments which support the uterus: weakness of the vaginal walls often occurs at the same time. The symptoms of uterine prolapse are low back pain and a heavy dragging feeling in the lower abdomen: these are often overshadowed by the distressingly embarrassing incontinence which results from lax vaginal walls. The stress of only a sneeze, a cough, or a giggle often causes the involuntary escape of urine. The cure is operative and very rewarding.

Discharge (*Leucorrhœa*). A white discharge is called leucorrhœa. It is normal for a woman to have a white odourless discharge: medical help should be sought if a discharge becomes offensive is unduly watery, is bloodstained or causes irritation. A discharge can originate in the Fallopian tubes and uterus, for example in pelvic inflammatory disease, but is more commonly due to an infection of the vagina by bacteria or fungi. A vaginal discharge causes the patient a great deal of discomfort and misery but as soon as the exact cause has been found treatment is speedily followed by cure.

The change of life or *Menopause* is the outward manifestation of a change in the hormonal balance in a woman's body: the periods stop and she can no longer conceive. Many women are very troubled at the prospect of the menopause, and this is not unnatural for nobody likes growing older. This natural apprehension is overlaid with all sorts of irrational fears largely based on "old wives' tales." Heavy losses of blood growth of facial hair, depression, loss of sexual pleasure, and frequent hot flushes are not an inevitable burden. The commonest symptoms are hot flushes and depression, but both are usually rapidly relieved by small doses of hormones especially if the woman consults her doctor when her symptoms first appear. At the menopause periods may stop rapidly or become irregular and finally cease: sometimes a woman misses one or more periods, then periods re-start and the cycle may be repeated several times before menstruation finally stops. The pattern at the menopause is as varied as woman herself—but if a woman has had no period for two years and then notices spotting or bleeding she should consult her doctor to make sure that all is well. The menopause has no influence whatever on sexual life (although naturally it has on fertility) and desire is not affected. It is recounted that a famous courtesan, at the age of 80, on being asked by Voltaire when women ceased to feel desire, replied, "I don't know—I haven't lived long enough."

Dysmenorrhœa or pain with the periods, is very common and most women experience this symptom at some time or another. Very often a girl's first periods are troublefree, but dysmenorrhœa develops after a year or two: this suggests that a psychological element is involved. Dysmenorrhœa is a symptom which has many varying causes, and the sensible thing to do, if pain is troublesome, is to see a doctor.

Amenorrhœa means stopping of the periods in a young woman. It may signify pregnancy or glandular disease or it can be purely psychological.

Abortion, or its more acceptable name, miscarriage, describes the spontaneous or induced termination of a pregnancy before the fœtus (baby) is able to survive. A baby cannot live unless it is born after the twenty-eighth week of pregnancy, though many infants born at this time die. The two main symptoms of abortion are bleeding and abdominal pain. Any bleeding occurring during pregnancy ought to be reported at once. Pain starts in the back and lower abdomen and is usually spasmodic in character, and like colic it works up to a peak and then temporarily passes off. Any pregnant woman with pain and bleeding should go to bed at once and send for her doctor. When doctors are convinced that a pregnancy should be terminated then an abortion by safe surgical means may be performed in hospital. *See* D42 (2).

CONTRACEPTION.

If a couple intends to practice birth control expert advice should be obtained from their family doctor or family planning clinic. The matter of whether or not a baby is born is too important to leave to chance. The method chosen must be effective as well as acceptable to the couple concerned, and the extent of the choice only emphasises the fact that the ideal contraceptive which is best for every couple at all times has yet to be discovered. The only method which is 100 per cent. reliable is abstinence. If the male seed (sperm) fertilises the female seed (ovum) then pregnancy results. Contraception is only effective if this union is prevented. A couple can achieve a measure of contraception without the help of pills or appliances if the husband practices *coitus interruptus* or they rely on the wife's "safe period." *Coitus interruptus* (when the man withdraws before emission occurs) is a thoroughly unreliable method which often leads to psychological difficulties in both partners. The "rhythm" or "safe period" method relies on estimating the time of ovulation and abstaining from intercourse during this time. This is at best unreliable, though its effectiveness can be improved by keeping careful records of the body temperature on waking each morning as the temperature rises once ovulation has occurred. The interpretation of these temperature records needs care and couples who must rely on this method can obtain expert advice from, for example, The Catholic Marriage Advisory Council, or a family planning clinic. *Barrier methods* prevent the sperms from reaching the ovum and can be used by the man (sheath or condom) or woman (cap or diaphragm); the reliability of the barrier is greatly increased if it is used in conjunction with a spermicidal cream, jelly, or pessary. A great many women have found that the *oral contraceptive pill* is ideal for their needs: it is the most æsthetic means of contraception and offers the most complete protection against pregnancy. Oral contraceptive pills contain chemical substances (œstrogen and progestagen) which replace the hormones normally released from the ovary while an ovum is developing. Ovulation does not occur, and without an ovum there can be no pregnancy. Pills must be taken strictly as directed as the dose is the lowest that will provide effective contraception and missing a tablet may result in pregnancy. Side effects sometimes occur (for example, nausea, breast discomfort, headaches,) but usually decrease after a few cycles of medication. Newspaper reports of the deaths of young women taking the pill have caused widespread concern. These tragedies have followed blockage of a blood vessel (by thrombosis or embolism) and have been carefully investigated, and the conclusions are that the number of such deaths is small and does not differ from the number which would probably have occurred in any case. No satisfactory pill for a man has yet been developed. In the newest method of contraception a small plastic *intra-uterine device* (loop, bow, or coil) is inserted into the womb. Once inserted it can be forgotten: a tremendous advantage to many different peoples and societies. It is not as effective as the pill but is more satisfactory than barrier methods. This intra-uterine device is not suitable for all women and is usually not recommended to women who have borne no children or who have very heavy periods. However, careful selection of suitable women has resulted in a high proportion of satisfied users. The search for the ideal contraceptive continues.

PART III. SPECIAL TOPICS

SPARE-PART SURGERY.

SPARE-PART surgery began when the first pre-historic man to survive a traumatic amputation of a limb attached a piece of wood to the remaining stump to help himself walk or grasp. It remained in this phase, with a few exceptions, until the present century, when the combined advances of many different aspects of medicine made possible the insertion of artificial materials and living tissues *into* rather than on to the body.

A notable exception to this recent development is the ancient use of skin grafts. It is often quoted that as long ago as the 6th cent. B.C. Indian surgeons were moving flaps of skin from the fore-head to the nose to repair severe nasal defects (usually a result of the punishment of "cutting off the nose"). The Italian, Tagliacozzi, gives a description of nose-repairing using grafts from the arm in a work published in 1597, and the *Madras Gazette* of 1792 describes in detail the rotation of a forehead flap to the nose. The old maxim "there is nothing new in medicine" comes to mind yet again.

Spare-part surgery can be divided into three sections:

(1) the attachment of devices to the outside of the body to replace missing parts (*external spare parts*);
(2) the insertion of parts made of foreign dead material into the body; and
(3) the insertion of foreign, living, function-ing tissue into the body (*internal spare parts*).

Each presents its own problems, the last being by far the most complex.

1. EXTERNAL SPARE PARTS.

It is not intended to discuss the tremendous advances that have been made in this field. Artificial limbs are being improved continually. For example, it is possible to make a power-driven upper limb that can be controlled by the patient from the electrical potentials developed in the muscles of the stump. Although such complex spares are seldom required by adults, they may be valuable to children, and the cripples of the thalidomide disaster have been a great stimulus and challenge to the limb-makers. One must not forget that spectacles, hearing aids, false teeth, and even wigs can be defined as external spare-parts. The benefit to mankind of this type of spare-part medicine is incalculable.

For the future this branch of spare-part medicine holds promise of the development of other artificial sense organs. Many years hence we may see an artificial eye relaying its message to the brain, for preliminary experiments have already been performed with this object in mind. Such progress will be especially important in the re-placement and bypassing of organs incapable of repair, such as the nerves from the eye and ear.

2. INTERNAL SPARE PARTS.

Dead and Inert Foreign Materials.

Artificial spare parts of metal, plastic, or dead tissues have been of most value in the replacement of those parts of the body that have a simple, relatively inert, mechanical function, such as arteries and joints. Three problems face the surgeon. The first is to insert the spare part with-out infection, for infection around a foreign body almost always results in its extrusion from the host. Secondly, the material inserted must be acceptable to the tissues. The chemical and the physical properties of a spare part are important. Vitallium and stainless steel evoke little tissue reaction, and most of the newer plastic materials based on nylon, Teryiene, or polyethylene none at all. Nevertheless, even an inert material if it is porous will evoke a foreign-body reaction in response to the changes of tissue and surface tension in and around the pores, and any constitu-ent that is at all water-soluble may cause inflam-mation. Thirdly, but by no means least, the material must be strong enough to withstand the enormous stresses of daily life. The strains placed on an artificial hip joint by a few years' weight-bearing are far in excess of the stresses and strains that we expect our motor-car engines to

withstand. Fortunately the newer metals and plastics are both inert and strong; indeed, much of this field of spare-part surgery could not have developed without the brilliant discoveries of the chemical and other industries.

Artificial Joints.

Since 1938, when Smith-Petersen found Vitallium to be a suitable metal for inserting into the body, many types of spare hip have been made. Metal cups have been inserted between the joint surfaces; the head of the femur (thigh bone) has been replaced; and in recent years complete joints have been inserted. The problem of wear due to friction, not so serious in the older operations where one surface was living and capable of self-repair, has not been completely solved and at the moment these spare parts are being inserted only in elderly patients. Time will tell how successful such operations can be. The production of a " frictionless " joint is now being pursued by many workers, and the complete replacement of the hip joint will probably soon be a common routine procedure.

Apart from the problem of wear at the joint surfaces the orthopædic surgeon (who deals with bones and joints) has also to solve the problem of making a permanent joint between the spare part and the bone. Occasionally the metal wears right through the bone or, more often, just becomes loose. Much work will have to be done before we have a spare part that the skeleton will accept without complaint. Probably this aim will not be achieved until the growth and metabolism of the host bone around the spare part can be controlled, and the stresses can be transmitted from it to the host in a more physiological manner.

Many other joints have been replaced, the finger joints in patients with severe rheumatoid arthritis, the elbow, and the knee. The problems are similar but greater than those of spare hips; fixing metal to bone becomes more difficult as the bones get smaller and the mechanics of the joint more complex.

Artificial Arteries

The replacement of arteries with artificial tubes has developed over the last 15 years. The techniques of joining vessels have been understood since the beginning of the century, but suitable materials with which to make artificial arteries have become available only recently. Fifteen years ago the enterprising surgeon simply sewed together two strips of man-made fibre cut almost literally from his shirt-tails, but now we have a vast array of vessel substitutes. Many are made of Dacron (Terylene). One difficulty with these tubes is that they kink when bent, and we still hope to develop a more flexible elastic graft. With such substitutes one can replace a segment of vessel knowing that the holes in it will be effectively stopped by blood clot; that a firm fibrous reaction will develop at the line of stitches to bind it to the host vessel; and that, provided there is enough blood flowing through, it will not become occluded by blood clot.

These grafts are not perfect. Thus, though the material is strong enough to withstand the arterial blood pressure for many years, it does not conduct blood as well as a normal vessel and thrombosis is a hazard. Partial replacement of an organ may fail because of the progression of the primary disease. As total replacement of all the vessels is impossible, we will continue to have late failures until we can also cure or arrest the underlying disease. It follows, therefore, that the aim of spare-part surgery should be the complete removal and total replacement of a diseased organ or system.

Artificial Heart Valves.

The aortic valve (*see* P27) is often so extensively destroyed by disease that repair is impossible. In such circumstances the damaged valve must be replaced with an artificial one or one from another person. The valve most commonly used is the Starr valve, made entirely of metal and plasti but freeze-dried aortic valve homografts, take soon after death, are also used. Both may b considered as inert foreign material, for the cells o the freeze-dried valve are dead and disorganise and do not cause an immune response.

Sometimes patients can be given three artificia valves—aortic, mitral, and tricuspid (*see* P27 This is as near as we can go at present toward giving them an artificial heart, but it is unlikely t be long before an artificial pump will be inserte as a long-term replacement for the myocardium

The heart valve presents another complicatio of spare-part surgery. The materials of which is made are inert when placed in soft tissues, bu not when placed in a continuous stream of bloo Whereas the normal valve falls back away fro the mainstream, when blood is ejected from th ventricle, the ball of the Starr valve lies right in th middle of the stream. Turbulent flow around th valve may cause sufficient destruction of red bloo cells to produce anæmia, and if the thrombu around the valve becomes infected, endocardit (*see* P30) will develop, which may be fatal.

It is in many ways surprising that either arti cial or freeze-dried valves function so well; son Starr valves have been in position for as long as years and the one-year success rate for the operations is now well above 70 per cent.

Artificial Hearts.

The " heart–lung " machine is both an artifici heart and an artificial lung, and is used extensive during cardiac surgery. It is only recently th very small pumps have been devised that can l left connected to the conscious patient to repla or aid the heart muscle for long periods.

When perfected these devices will be used wh the muscle is so weak that it is unable to functi properly following the repair or replacement chronically diseased valves, or after infarcti (P30) of the heart muscle. Thus such a device not an artificial heart, just a temporary artifici left ventricle—though it represents the beginnin of another new field of spare-part surgery.

Artificial Nerves.

For the Heart. The commonest conductio system to be replaced with an artificial device the conducting system of the heart. Failure ventricular contraction due to a permanent transient heart block results in a fall in bloo pressure and collapse. Conversely, the san result will occur if the heart-beat becomes exce sively fast. In either case, whatever the cause, is necessary to control the heart rate to mainta life. An artificial pacemaker takes over from th natural one. The battery and timing devi replace the natural pacemaker (sino-auricul node) and wires replace the special conducti fibres of the normal heart, the ends of the wir being placed on that portion of the heart that o wishes to control—usually the ventricle.

The problems of implanting wires and fixi them to the heart are no different from tho already discussed, but a new problem arises—t source of power. Early models had the wir coming to an external electrical source, and te porary pacing is still done in this way. This unsuitable as a permanent method, as the site which the wires come through the skin is extreme susceptible to infection. Permanent pacing therefore achieved with either long-life implant batteries (needing regular renewal) or by indu tion. In the latter system the wires from th heart are brought to a coil beneath the skin a current is induced therein from an overlyi primary circuit. The source of power is th external, removable, and without any dire connections with the internal secondary circu (Fig. 1). This overcomes the problems of seps breakage of wires, and renewal of power suppl Recently attempts have been made to harne electric current produced within the body as source of power.

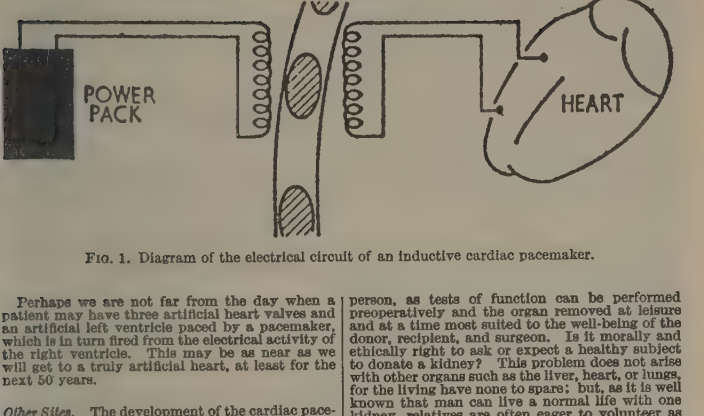

FIG. 1. Diagram of the electrical circuit of an inductive cardiac pacemaker.

Perhaps we are not far from the day when a patient may have three artificial heart valves and an artificial left ventricle paced by a pacemaker, which is in turn fired from the electrical activity of the right ventricle. This may be as near as we will get to a truly artificial heart, at least for the next 50 years.

Other Sites. The development of the cardiac pacemaker is far ahead of all other artificial nerve implants. Electrodes have been implanted on the bladder to stimulate micturition in paraplegics, and attempts have been made to control the sphincter of the bladder to prevent incontinence of urine. Anal incontinence has also been studied, and the most promising approach is the stimulation of the sphincter from the outside with a dumb-bell-shaped electrode fitted into the anal canal. These efforts will no doubt lead to the development of permanently implanted electrodes with external inductive power circuits to maintain sphincter competence but which allow it to relax on demand.

A final example of the way in which man is attempting to take over the nervous control of the body is the study of methods of pacing the nerve to the carotid sinus. The carotid sinus is a "baroreceptor" which monitors the blood-pressure and transmits information to all the various mechanisms which help to avoid unwanted changes in pressure. By pacing the nerve transmitting such information, the aim is to regulate blood-pressure artificially.

3. INTERNAL SPARE PARTS.

Living Tissues.

In many instances we have within ourselves the tissues required to fashion a spare part. Flaps of skin can be fashioned into new noses, the ileum can be made into a bladder, the colon can become an œsophagus.

The use of host tissues depends to a large extent on the ingenuity and technical skill of the surgeon. Provided the blood supply of the part remains intact or is re-established, the tissue will live, and often shows a remarkable degree of adaptation to its new function.

Living Foreign Tissue.

The problems of placing living foreign tissue into the body are those outlined for inert materials, with the addition of several greater ones, all yet to be fully resolved. Thus, first, one must obtain suitable material. Second, the latter must be kept alive during transit from donor to host. Third, it must be kept alive within the host. These problems are best discussed in the context of renal (kidney) transplantation.

Source of Materials.

Organs for transplantation must be living and healthy. The obvious source is another living person, as tests of function can be performed preoperatively and the organ removed at leisure and at a time most suited to the well-being of the donor, recipient, and surgeon. Is it morally and ethically right to ask or expect a healthy subject to donate a kidney? This problem does not arise with other organs such as the liver, heart, or lungs, for the living have none to spare; but, as it is well known that man can live a normal life with one kidney, relatives are often eager to volunteer as donors. Donation is not, however, free from risk. Nephrectomy (removal of the kidney) has its hazards, such as hæmorrhage, in addition to those associated with all operations, such as pneumonia and pulmonary embolism. After the donor has survived the operation there is still the possibility of an accident or disease process affecting the function of the remaining kidney. Against these problems must be set the undoubted fact that transplants from live, related donors do better than those from dead, unrelated donors. The problem is one for the individual surgeon concerned. Obtaining kidneys from dead bodies has its problems. The best source is the recently dead young person, but there are legal problems concerning the rights of the relatives. Most relatives, however, agree to the removal of a kidney.

Preservation of Organs.

Whatever organ is used, and whatever its source, it inevitably undergoes a period of ischæmia (being without blood) between removal and insertion. The effects of this ischæmia are minimised by keeping it as short as possible and by keeping the organ cool. A cold kidney (4°C) can survive six hours or more of total ischæmia and function. A warm kidney is severely damaged after 30 minutes, but may still recover after one and a half hours of ischæmia.

Any organ must of course be removed in aseptic conditions, and if the donor is alive this is done as an elective procedure in an operating-theatre adjoining that in which the recipient is being prepared. The kidney is then carried from one room to the next, and the ischæmia time is that which is needed to make joints in two blood vessels (10–20 minutes). With cadaveric donors the preparation of the recipient takes longer, as it is begun as an emergency after the donor has died. The kidney is therefore washed through with cold saline solution and kept in ice until the recipient is ready.

In ideal conditions a transplanted kidney will produce urine as soon as the clamps are removed from the blood vessels. There may follow a diuretic (high output) or anuric (low output) phase, depending upon the degree of tubular death in the kidney.

Preparation of the Recipient.

Surgeons like to operate on a fit patient, for an ill one is more susceptible to all the common post-operative complications. Patients in kidney or liver failure are not usually subjected to operation,

but in transplantation these are the very subjects with whom the surgeon has to deal. The immediate success of kidney transplantation is entirely dependent upon the efficiency with which an artificial kidney can bring the patient back to a normal condition before operation. Careful use of the artificial kidney gives a fit patient who can withstand surgery and the necessary postoperative medication. Without such preparation the mortality rate is high.

There is no machine to replace liver function, and hence liver transplantation is performed on sick patients. Passing the patient's blood through a pig or human cadaveric liver has not been outstandingly successful in the treatment of liver coma. Once an artificial liver is available to prepare the patient, liver transplantation will become a practical proposition.

Surgical Techniques.

Joining the vessels of the graft to those of the host is a fairly simple procedure requiring the basic skills of vascular surgery. In the case of the kidney, there are three large tubes to join: the renal artery, renal vein, and the ureter. Each is joined to its counterpart in the host, except that in the case of the blood vessels, any suitable sized vessel will do, and the *internal* or *common iliac* vessels are more convenient than the patient's renal vessels.

The transplantation of other organs, such as the liver or the lungs, is more difficult, as there are more (usually smaller) vessels to join.

The development of the techniques of transplantation have depended upon work in animals. Many thousands of renal, liver, heart, and lung transplants have been performed in dogs and kidney and liver techniques perfected, so that the practical problems of inserting the graft into the recipient are now the least of the transplanter's worries.

Prevention of Rejection.

Once inside the recipient, perfused with recipient blood, the transplanted organ is subjected to the major hazard of this whole problem—namely, that of host rejection.

From a very early stage in interuterine growth special cells develop, particularly in the thymus, which are capable of recognizing any protein which is foreign to the body. They then migrate to populate the so-called reticuloendothelial system. These "self-recognising" cells can initiate a series of responses by which any "non-self" material is destroyed. This, in very simple terms, is the basis of immunity (*see* P63). Any cell capable of initiating an immune response is called an immunologically competent cell.

Foreign tissue is destroyed either by antibody production or a local cellular reaction. It is thought that the local cellular response is the most important line of defence. Circulating antigens are released by implanted tissues, but in small amounts, so that there are probably only low levels of circulating antibody.

If one accepts this mechanism of graft rejection then a number of methods of preventing this response become apparent. Only two are of practical value today.

Make the Graft Non-antigenic. Homozygous (identical) twins have an identical genetic make-up. Tissue grafted from one to the other is totally accepted. The results of kidney transplants between identical twins are excellent, some functioning 6–8 years after transplantation. Such good results justify the use of a living donor, but regrettably few patients with kidney failure have an identical twin.

Attempts are being focused on ways of typing the tissues of both donor and recipient to get the best degree of immunological compatibility. These studies are in their infancy and involv many sophisticated techniques.

Recipient and donor should have the sam blood group. White blood cells can also b "typed" in the same way as red cells, but this is much more difficult procedure.

A host-versus-graft reaction can be detecte before transplantation by injecting the recipient lymphocytes (P24) into the skin of the donor an observing the local reaction. This test can be use only with living donors.

Prevent the Host Recognising "Non-self Material. Once a foreign tissue is in the body an has acquired a blood supply from the heart, ther is only one way to stop the host recognising an starting an immune reaction against it—to destro those cells involved in the recognition proces This is known as immunosuppression. The sma lymphocytes are the target cells and there ar three possible methods of attack.

Irradiation. Total body irradiation was th first method to be tried, but was given up when i was found that the dose required to achiev effective immunosuppression invariably killed th host. Local irradiation of the graft is use occasionally to help suppress a severe rejectio phase.

Cytotoxic Drugs. Many drugs have bee studied, but by far the most successful is azathi prine (Imuran). Imuran will destroy all types o white cell, and complete depression of marrow an lymph-node activity can occur if the dose is no carefully controlled. Cortisone has an inhibitor effect on the reticuloendothelial system and is use in combination with azathioprine. The othe cytotoxic drug in common use is actinomycin C.

The present-day successes of kidney trans plantation are due either to chance tissue compat ibility or the control of rejection by azathioprin and cortisone, but better substances are needed.

Antilymphocyte Serum. The wholesale destruc tion of bone marrow and lymphoid tissue is a blunderbuss approach. Antilymphocyte serum can specifically destroy those cells believed to b responsible for graft rejection. It is made b injecting human white cells into the horse and then preparing the anti-serum in just the same way tha the antisera against many bacteria are made Preparations can now be made of pure anti lymphocyte globulin. As white cells from many different subjects have to be pooled to get enough for an adequate antigenic stimulus, the antiserum is species—but not individual—specific.

Studies with this substance in man are jus beginning; those experiments that have been performed show great promise. Antilymphocyte serum is the only specific immunosuppressiv agent yet developed and those patients who have received it both preoperatively and post operatively have shown a worthwhile improvement in their tolerance to the grafted kidney.

The one-year survival rate of the graft is con tinually improving. Figures of 80 and 90 per cen have been claimed, while the overall world figure for living related donors is about 70 per cent—fo unrelated cadaveric donors the figure is about 5 per cent.

Liver Transplantation.

A few livers have been transplanted between humans and many have been exchanged between dogs. The latter work has shown the procedure to be technically possible and that the problems of rejection can be met in the same way as kidney transplants. Many animals have survived sh months, some as long as a year and a half, but there are no long-term survivors in man.

The functions of the liver are more complex than those of the kidney and certainly less well under-

stood. Thus, though the blood of a man in hepatic coma (unconsciousness due to liver failure) can be passed through another human or pig liver to lower the concentration of bile pigment and ammonia, there is often no change in the level of coma. A fully functioning transplanted liver would presumably restore a patient in liver failure to normal, but this has rarely been achieved for even a short term.

At present anyone attempting liver transplantation for hepatic failure must work with a very ill recipient, and the chances of success are slight. With the kidney this problem was overcome by the development of the artificial kidney; little progress can be expected with liver transplantation until we have an effective artificial liver. It would help in the making of such a machine if the biochemistry of hepatic coma were more fully understood.

Liver transplantation will become a practicable procedure when the problems of temporary support for the patient in liver failure and the rapid collection and perfusion of the cadaveric donor liver have been solved.

Other Organs.

The transplantation of the heart, lung, pancreas, gut, and endocrine glands are all technically feasible procedures. An ape heart has been inserted into a man, though its function quickly failed. At the time of writing (February 1968) the second human heart transplant carried out by South African surgeons was reported to be functioning five weeks after operation. One patient has had a successful pancreas transplant. So continued progress is being made. Any organ that can withstand being without a blood supply for 30 minutes may be transplanted, and as our knowledge of the immune reactions increases so these transplants can be kept alive for longer periods.

Other Tissues.

Perhaps the most important body tissue to be transplanted, and certainly the one that has made all the recent developments of transplantation possible, is blood. Blood transfusion is a form of tissue transplantation, the value of which is inestimable. A major part of modern surgery could not be done without it. The transfer of blood-cell-producing tissues, the bone marrow, has not been so easy. It is beset with all the problems of organ transplantation. Experiments have shown that antilymphocyte serum will improve the results of bone-marrow exchange. If a diseased blood-forming system could be completely destroyed and replaced with a healthy one a great number of diseases such as aplastic anæmia (P25) and leukæmia (P26) might become curable.

The future of transplantation is bright. Solving the problems of immunity will solve many of the fundamental problems of cellular biology. Transplanting organs successfully will give life to many. All this will repay the singlemindedness and courage of the few who have pressed on in this field during the last twenty years in the face of failures, discouragement, and seemingly insurmountable barriers.

CONGENITAL MALFORMATIONS (TERATOLOGY).

At the end of 1961, reports began to appear in medical journals of malformed children, born to mothers who had taken the drug "thalidomide" during their pregnancy. These reports, and those which followed in the next two years, demonstrated yet another hazard to which the developing fœtus might be exposed—substances taken by pregnant women which were active teratogenic agents, *i.e.*, substances inducing abnormal formation of organs and tissues. These tragic events drew renewed attention to a subject that had been studied for many centuries: the origin of abnormally developed children. Various collections of malformations had been made from the 16th cent. onward culminating in Taruffi's *Teratology* in 8 volumes (1881–1895), but it was between 1880 and 1900 that the Leipzig anatomist, Wilhelm His, described a number of abnormal young embryos, in order to investigate the possible mechanisms of development of various abnormalities. Others extended this work and noted that many early embryos showed defects also seen in deformed still-born or live-born infants (for example, deformities of the extremities or of the brain and spinal cord, such as *spina bifida*, *anencephaly*, etc.). It was realised that early disturbances of fœtal growth might cause similar abnormalities to those found in abnormal individuals, and that the death of the embryo in instances of severe interference with growth was a change different only in degree from that which might cause a malformation. Almost a hundred years before these observations were made, G. St. Hilare had produced abnormal chick embryos by pricking them with needles introduced through holes in the shell, or by varnishing the egg to exclude oxygen. These early experiments and those of Driesch, who induced the formation of "twins" in sea urchin eggs by placing them in warm water, represented the beginnings of the science of experimental teratology which has, in recent years, made a considerable contribution to our knowledge of early mammalian development.

The factors that cause malformations may be divided into those which act *via* the genetic constitution of the embryo, and those which are a result of changes in the intra-uterine environment. While it is with these latter factors that this discussion is concerned, it should be pointed out that abnormalities of the *x* and *y* chromosomes (sex chromosomes) or of the other 22 pairs of chromosomes (autosomes) may give rise to characteristic syndromes or malformations. These abnormalities will not be further considered except to say that the majority of autosomal abnormalities are probably lethal, and that relatively few embryos which are abnormal in this respect survive to give rise to abnormal infants. The large list of agents potentially harmful to the fœtus is growing, as more information is obtained from experimental work. Virus infections, radiation, drugs, chemicals, hormones, malnutrition, and physical injury have all been shown to be capable of producing abnormalities of development under appropriate circumstances. A number of agents of this kind will now be considered and their possible mode of action described where it is known. It must be emphasised that although many teratogens have been described, very little is known about their method of action.

Virus Infections.

An Australian opthalmologist (Gregg, 1941) was the first to realise that an epidemic of German measles (rubella) had resulted in the production of an abnormally large number of infants with eye defects, born to mothers infected with the causative virus in the early stages of pregnancy. These findings, and the association of German measles with other malformations, notably of the heart and ears, have since been amply confirmed and extended. Many other viruses have been shown to pass from mother to fœtus, but evidence incriminating any other virus in teratogenesis in man is lacking. Although virus infection during pregnancy may be associated with the birth of an abnormal child, these infections are so common, and high fever, drug administration and metabolic disturbance such common features of the accompanying illness, that a number of "red herrings" are introduced into any study of viral teratogenesis.

In an effort to overcome these difficulties, prospective studies of large numbers of women during pregnancy are being carried out. In these studies, the large number of individuals who are infected without any evidence of clinical illness are also detected. The method used is to take blood samples in the early and late stages of pregnancy and to test for the presence of antibodies to infective agents in both samples. Any change, either

the development of an antibody not present in the first sample, or a significant increase in antibodies already present, may thus be observed and provides evidence of infection. In this way, a recent study in the United States of America has provided some evidence of a possible relationship between Coxsackie B_4 virus infections ("Flu"-like illnesses with sore throats) and the occurrence of congenital heart disease, but the relationship is not yet proved.

Radiation.

Ionising radiation is a normal part of our life in the form of isotopic sources in the earth, irradiation from outer space and the small doses to which we are exposed during chest and dental X-ray procedures, etc. Very extensive studies of the effects of radiation on embryonic development have been made in animals. All stages have been examined and the effects of radiation on sperm and ova also observed. Some important points have been demonstrated in these experiments. In general it may be said that so-called "harmless" doses are probably not without biological effect, and may act by potentiating genetic factors associated with malformation. This has been shown to occur in the mouse by L. B. Russell, who found that a strain of mice occasionally showing skeletal abnormalities, produced rather more abnormal offspring after low dosage irradiation. Direct effects of larger doses have unfortunately been studied in man. Japanese children *in utero* at the time of atomic explosions who were exposed to varying doses of irradiation, showed evidence of impaired growth, small head size and occasionally mental retardation. Other reports have shown an association between irradiation *in utero* and cerebral abnormalities at high dose levels. Intra-uterine irradiation associated with diagnostic X-rays has also been found to be dangerous to the fœtus, although in a less direct way. There is evidence showing that children irradiated during pregnancy are more likely to develop a malignant tumour in childhood than are normal controls. Although all of these facts point to the obvious precautions necessary with regard to irradiation and pregnancy, it should be emphasised that direct irradiation probably plays a small part in teratogenesis in man. More important is the effect of "background" radiation in potentiating other biological factors.

Drugs and Malformations.

Thalidomide: The abnormalities induced by thalidomide include absence of limbs, gross shortening, and absence of bones of the forearm. The malformations are generally bilateral and symmetrical, and the arms are involved more often than the legs. Heart disease, abnormalities of the eyes and external ears, and kidney malformations may also be produced by this drug. Very small doses of the drug are teratogenic; a case is reported in which a woman took two 100 mgm. tablets on the fortieth day of her pregnancy and later gave birth to a child with deformities of all four limbs. This extreme sensitivity to the drug has been confirmed by other case reports. It is also true that administration of the drug produces abnormalities in almost 100 per cent of the fœtuses exposed, provided it is given at the critical period of development. From a number of careful studies it is apparent that this danger period in man is from the 34th to 50th days after the last menstrual period. Early dosage causes ear and cranial nerve abnormalities (days 34–38); upper limb malformations occur later (39–44 days), followed by lower limb anomalies (42–48 days). At about this time (40–45 days), most heart defects probably occur. How the drug works on the embryo is uncertain, but in experimental work this compound has been shown to inhibit cell growth and division. Perhaps one of the most disturbing facts about the entire thalidomide disaster is that the drug was developed as a "harmless" sleeping tablet which was non-addictive and which, even if accidentally taken in enormous quantities, did not kill. These virtues led to the widespread use of the compound, thus adding to the size of the disaster. Since these events, all new drugs are now examined routinely for possible teratogenic effects. The only really safe course, however, is to avoid drugs of all kinds during pregnancy, unless they are absolutely necessary.

Other Compounds.

Hormones.

1. *Insulin:* The children of diabetic mothers are a special group in several respects. Recently however, a characteristic bony deformity of the ileum has been described which is possibly related to the administration of insulin to the mother. This association cannot yet be considered proved but it is certain that insulin has allowed many diabetic women to have normal children who would otherwise not have been well enough to undertake pregnancy.

2. *Cortisone and Related Compounds:* Although these hormones are capable of producing cleft palate in rodents, there is no evidence to implicate the drugs in teratogenesis in man. In general just as in diabetes, the conditions for which these compounds are given have a greater immediate relevance for the continued survival of mother and baby.

3. *Anti-thyroid Drugs:* These drugs, given for overactivity of the maternal thyroid gland, are able to cross the placenta and may thus act against the fœtal thyroid, causing a diminution in the output of thyroid hormone. After this, the pituitary gland of the fœtus produces more thyroid stimulating hormone and the thyroid is thus forced to grow excessively, often producing a goitre (which may even affect the normal process of delivery). This effect cannot be regarded as truly "teratogenic" but indicates an alternative mode of action for some compounds, *i.e.*, indirectly via the developing glands of the embryo.

4. *Sex Hormones:* In the same way, these compounds, sometimes given to prevent abortion in early pregnancy, may produce masculinisation or feminisation, depending on the compound and the sex of the child.

Cytotoxic Drugs (substances inhibiting cell growth and division): These are used primarily in the treatment of malignant disease but are also used to suppress the immune response in diseases of "auto-immune" origin, such as some kinds of kidney disease. All compounds which are effective in treating malignant diseases are capable of disturbing the division and growth of primitive cells. Thus, they will affect fœtal tissues as well as those of a malignant tumour. Many species of animals have been used in experiments with these drugs and most major malformations may be produced. There have been several reports of abnormal children born to mothers treated with cytotoxic drugs for malignant disease.

Antibiotics: Although sulphonamides, streptomycin and penicillin, and tetracycline have all been shown to be teratogenic in animals, there is no evidence of teratogenesis in man. Tetracyclines, however, must be considered as potentially dangerous drugs in pregnancy. Tetracycline crosses the placenta and may discolour fœtal teeth and inhibit bone growth. Its effect in man should be more closely watched.

Other Compounds.

Some naturally occurring agents may be shown to be teratogenic in animals. 5-hydroxytryptamine is a compound which, in man, is important in the control of small blood vessels. If given to rats during pregnancy, the changes in vessel tone in the uterus reduces blood flow to the placenta and malformations may result. It is easy to speculate that this type of change is responsible for many anomalies in man, but it is not, at present, possible to test this hypothesis.

Experimental Teratogens.

A number of compounds, never administered to man, are teratogens. Despite the apparent lack of relevance of these compounds to human malformations, a great deal of valuable information has been obtained by using them experimentally. The dye, trypan blue, has been found to produce heart defects in rats which resemble those seen in man. These defects are found to be due to improper folding of the heart tube. Early in development, the heart is a straight, contractile tube which gradually folds and divides into four chambers. If this folding is imperfect, the relative positions of the chambers change and the vessels which enter or leave them may thus be forced to take up abnormal relationships with surrounding tissues. By studying this abnormal situation in animals, much may be discovered about the mechanical production of defects in man.

Another example of this kind, relating to kidney malformations, has been investigated by Monie. He found that a certain cytotoxic drug prevented proper development of the vertebral column. This resulted in failure of certain vessels to develop normally, and the kidney, which normally develops in the pelvis and moves up the posterior abdominal wall in later development, remained in the pelvis resulting in "ectopic kidneys", *i.e.*, those in abnormal situations. These are most often situated in the pelvis in man.

An important general point can be made from experimental work. Identical malformations may be caused by the administration of many different compounds, or as a result of several different pathological processes. In other words, not all similar malformations need necessarily have a common cause. Elimination of a particular teratogen (*e.g.*, Rubella virus, by the development of a vaccine), may reveal the existence of other dangerous agents. Only constant attention to the prevalence and type of malformation seen in a given population will allow early recognition of any new factor, and this can only be done by keeping careful registers of cases, much in the way that epidemiologists study the spread of infections.

Immunological Aspects of Intra-uterine Life.

One of the most rapidly expanding areas of medical knowledge is that of immunology (*see below*). This science, which deals with the ability of the body to defend itself against infection, has an immediate relevance to teratology, since many of the mechanisms involved in immune responses are probably important in development.

If an organ, or part of a tissue, is transplanted from any individual to another, it will be "rejected" by the recipient unless the two individuals concerned are identical twins. This phenomenon (Homograft rejection), although capable of modification by various measures, holds true for all tissues which depend on cellular activity for their continuing existence. The cornea of the eye is an example of a tissue which does not depend on living cells in this way, and therefore may usually be transplanted without rejection. However, although the success of corneal grafts and some bone grafts are explained by this qualification, no such mechanism explains the tolerance of the foetus by the mother. Either the foetus represents a graft and the mother the host. Various research workers have demonstrated that foetal cells, which are composed of genetic material from father and mother, are capable of exhibiting "histocompatibility antigens", *i.e.*, recognition markers that allow the body to distinguish "self" and "non-self" components. Despite this, and the ability of the mother to "reject" homografts, the foetus is tolerated. The reason for this protection is not certain but is probably related to the ability of the cells forming the placenta—*i.e.*, those in contact with maternal tissues—to "mask" their antigenic determinants by a surface layer of mucoprotein. This type of cell recognition mechanism is of great interest to researchers in experimental teratology. Much of the process of development of tissues might be explained on the basis of an increased tendency of cells with a similar "identification" pattern to associate together. In this context it has been shown that if foetal liver cells and heart cells are separated to form collections of single cells, they will aggregate into groups of "liver" and "heart" cells, rather than at random. Further, when mixed antigens from several organs are injected intravenously, they have been shown to be more likely to go to the organ from which they were derived. It is possible that these effects are the result rather than the cause of differentiation, and are thus in no way responsible for the changes that take place. Another alternative is that the sites on the cell surface responsible for antigenic markers are different from those involved in recognition by cell to cell contact. It is along these lines that much recent work in teratogenesis is directed. The results have an obvious relevance in other diseases of man, notably the malignant transformation of tissues to form tumours, for in these tissues a population of cells has escaped from the normal control mechanisms that prevent unrestrained growth. It is essentially the normal inter-relationships of cells that must be maintained for the normal development, growth, and continued existence of man.

In summary, a great many substances have been shown to be potentially teratogenic, but the mode of action of the majority is not understood. It is evident from the information available to date that no drug should be taken during pregnancy unless it has been specifically prescribed for the individual concerned. In this way, unnecessary self-administration of potentially dangerous compounds will be reduced.

IMMUNOLOGY.

The mechanisms of the response of the animal body to infection is the broad field of study of the immunologist. For centuries it has been well understood that a second attack of some diseases is unknown or at least exceedingly rare. Those recovering from the plague could nurse fellow sufferers with impunity. Similarly those who recovered from quite mild smallpox were immune to even the most severe form occurring in devastating epidemics.

The basis for understanding, and therefore of utilising beneficially, this interesting phenomenon developed during the later years of the last century. First came the recognition under the microscope of specific "germs" or organisms responsible for many of the infectious diseases, then the demonstration in 1890 by von Behring and Kitasato of specific "antibodies" (to tetanus toxin).

Antibodies.

Following survival of almost any infection natural or experimental, substances can be demonstrated to have appeared in the bloodstream which act in some way against (anti-) the infecting organism. The techniques to demonstrate the existence of these antibodies are often complex as they are of many different types. For example, the serum of a patient who has suffered from typhoid fever will contain an antibody capable of agglutinating (clumping together) a suspension of the specific organism grown on artificial media—even a suspension killed by heat or chemicals. Depending upon the severity of the infection and the individual this agglutination may occur even when the patient's serum is diluted 1:1,000 or more. Again, some organisms produce toxins (poisonous substances specific to the organism) often acting specifically on heart, muscle, or nervous system. Tetanus or lockjaw (due to infection of a wound with *Clostridium tetani*) is a very serious, often fatal, illness caused by a powerful toxin elaborated by a relatively small number of organisms. An antibody (in this case specifically an antitoxin) can be produced artificially in an animal, and if its serum, after suitable purification, is injected into the human sufferer it will prevent or cure the illness provided, of course, the necessary surgery is carried out on the wound.

Antigens.

Typhoid infection or injection of the causative organism *Salmonella typhi* causes the generation

of antibodies; the organism is said to be antigenic, *i.e.*, to have stimulated antibody response. A rather milder disease is paratyphoid (caused by *S. paratyphi*) and the antibodies produced in this disease are different and do *not* react with *S. typhi*. Furthermore it was soon discovered that there is not one but three types of *S. paratyphi* designated A, B, and C! This is in some ways a help and in some ways a hindrance. It may aid the epidemiologist studying an outbreak to track down the source and to exclude from his considerations sporadic cases of different types. But at the same time it complicates the production of vaccines (*see below*).

Again there are many other species of the *Salmonella* group of organisms causing "food poisoning" of varying severity. All these species have antigenic differences and can be separately identified using suitable prepared sera and this provides further help for the epidemiologist tracing the source of an outbreak. (*See also* Other Antigenic Substances, P65).

Immunisation.

Experiments show that if a group of animals or humans is given small doses of an organism and thus caused to produce antibodies, then "challenged" with a much larger dose of the same organism there is a highly significant difference in the degree of illness between the pre-treated and the untreated group. In the pre-treated group there may be a much milder illness or a high proportion of the group may not develop an illness at all (depending on which particular group of organisms is being investigated). The performance of this pre-treatment—safely—is the basis of modern immunisation procedures.

(1) *Killed Vaccines.* The safest way is to inject beneath the skin a suspension of the dead organism. Such a *killed vaccine* for typhoid was employed by Almroth Wright in 1897 at a time when large numbers of soldiers were dying of the disease in the war in South Africa. His vaccine was killed by heat and preserved with 0·5 per cent phenol. The modern vaccines are prepared by killing with 70 per cent alcohol and preserving in 25 per cent alcohol. The final concentration of organisms is about 1,000 million *S. typhi* and about 500 million each of *S. paratyphi* A, B, and C per c.c. The vaccine is given in two doses, the second twice the size of the first, with a month's interval between. The injections often produce temporary malaise but not illness, certainly no intestinal illness. The degree of protection is good and can be maintained by "booster doses" at intervals of 1–3 years. Similar vaccines can be prepared against plague and cholera and, using different methods for killing the organisms, many other diseases.

(2) *Attenuated Vaccines.*—With some organisms even the most careful and gentle techniques of killing them in some way alters their antigenicity. In the case of some of these it has been possible to use an "attenuated" organism, *i.e.*, an organism which for some reason has lost the power of producing severe disease. Edward Jenner published in 1798 his observations on the protection against smallpox given by either inoculation with, or infection by, cowpox. In earlier centuries and other countries where the disease was a permanent feature of life and epidemics often reached devastating proportions, children were inoculated with material from an actual pustule from a mild case of smallpox. Jenner's method was infinitely safer and after initial fierce opposition gained wide acceptance. With a modified vaccine and technique it is in use to this day. Pasteur was a very great experimentalist but he discovered the first method of *artificial attenuation* in much the same way as Fleming discovered Penicillin—by accident. A culture of chicken cholera bacillus was left on the bench during a summer holiday instead of being regularly sub-cultured and incubated. It failed to produce cholera on inoculation into chickens but at the same time caused them to develop an immunity which protected them completely from a fully virulent organism—one which killed other chickens. Pasteur was then spurred on to search for other methods of attenuation. Culture of organisms at higher than usual temperature succeeded with anthrax—a very fatal disease of sheep and cattle. Of recent years similar attenuation has been attained by rearing viruses (infective agents very considerably smaller than bacteria) in cultures of living cells for many generations. The strain of yellow fever virus (called 17D) grown in chick embryo tissue cultures is in worldwide use as a vaccine. It is immensely effective, immunity lasting for at least 6 years after a single dose. Yellow fever caused the deaths of many thousands of workers during the building of the Panama Canal; all this loss of life could have been prevented if the vaccine had been available then.

Pasteur developed a technique for attenuating the virus of rabies (hydrophobia), a widespread very horrible, and usually fatal disease in France and indeed all Europe at that time. The disease results from the bite of a mad dog or wolf, the bite inoculating the virus which is in the animal's saliva. Pasteur could not demonstrate the organism, it was far too small to see, but he could demonstrate the *infectivity* of the saliva. Further more he appreciated that, although the saliva was infective, the main home of the disease was in and by the spinal cord. He therefore dried the spinal cords of infected rabbits in air for varying periods. By injecting an emulsion made from these cords first those dried for a long period and then those for less and less time he was able to protect dogs from fully virulent virus—"street virus." Just think of the difficulty of catching mad dogs off the street and collecting their saliva at a time when no treatment was available if you were bitten! Such bravery was rewarded when in July 1885 the boy Joseph Meister was brought to Pasteur having been bitten many times by an undoubtedly rabid dog. The boy was injected with graded doses of the spinal cord emulsion over the succeeding days and survived to serve as gate porter at the Pasteur Institute for many years in later life. An important feature of this disease in this context is the long incubation period—1–3 months between being bitten and developing the illness. This long period allows time for the serial injections necessary with Pasteur's method. With most infectious diseases the immunity must be raised *before* the date of infection.

The search for attenuated viruses and methods of artificially attenuating viruses is now very "big business." The current vaccine for poliomyelitis (infantile paralysis) vaccine is a live attenuated vaccine and has the enormous advantage that it can be given by mouth—on a lump of sugar. The formol-killed vaccine formerly used cannot be given by mouth because its antigenicity is destroyed by the digestive processes. However, the living virus can survive because indeed this is its natural route of entry into the body—through the wall of the intestinal tract. This search has also yielded strains of measles virus which are antigenic but produce only minor illness. Measles itself is to us a mild disease and you may think it strange to bother about a vaccine but in some undeveloped regions measles can cause very severe epidemics with a high mortality rate.

(3) *Passive Immunisation.*—The third method of immunisation, formerly very important, is *passive* immunisation. By passive immunisation is meant the transfer to a patient of an immune antibody from another person already immunised or indeed from an immunised animal. It is passive in that the patient does not have to produce actively his own antibodies which takes time, and could mean a delay of days or weeks. The immense advantage is that the treatment is immediately effective. Antitoxins are extremely effective in this way; in particular diphtheria and tetanus antitoxins have saved thousands of lives over the years. The effect is immediate but only short-lived and this is the first disadvantage; the dose must be repeated quite frequently. Second, as it is only an antitoxin it neutralises the effect of the toxin but does not affect the diphtheria, tetanus, or other organisms themselves—they must be eradicated by other means. Third, the antitoxins are very specific; it is simple enough to know whether to use anti-diphtheria or anti-tetanus serum from the clinical findings but the case of pneumococci

pneumonia it is not such a simple matter. A large number of antigenically different types are found and even though group polyvalent antisera can be made the group of the organism isolated from the sputum or phlegm must be known before effective treatment can be started (*see also later*). This brings us to our fourth disadvantage—to have sufficient quantities of these antisera they must be produced in animals, commonly horses. Hence a "foreign" protein is introduced into the patient and this in itself acts as an antigen (*see below*).

With a few exceptions antitoxins are less important now that antibiotics such as Penicillin and Streptomycin are available and can rapidly eliminate the organisms themselves. However, convalescent serum can be used, that is serum from a patient who has recently had the disease or in fact has recently been actively immunised and shown, by laboratory testing, to have given a good response. This can be valuable in aborting an attack of measles, for instance, when an epidemic breaks out among children already suffering from some other disease, as perhaps in hospital. Similarly some people cannot be vaccinated due to a skin condition such as eczema but in a smallpox epidemic they can be protected. However, this protection is brief and the serum always in short supply, so that the indications for its use have to be very strong indeed. Modern methods of protein fractionation can provide an even more potent and pure protective agent—immune γ globulin—to be discussed later under **Antibody Detection**. This is difficult and expensive to produce and therefore also in short supply.

There is one stage at which we are all largely dependent upon passive immunity and that is during the first few months of life. Antibodies transferred from the mother across the placenta to the infant, perhaps reinforced by antibodies taken in with the mother's milk, render the infant relatively immune during the first six months of life to the acute infectious fevers and other diseases to which the mother had a strong immunity.

Other Antigenic Substances.

So far we have only discussed antibodies to *whole organisms*, living or dead, and their products, such as toxins. In fact almost any protein, strange to the animal into which it is injected, will cause production of an antibody. For instance, rabbit blood injected into a goat will cause the production by the goat of an "anti-rabbit" antibody. This is the basic fact preventing the easy grafting of organs from animals to humans. It is the basic difficulty in the extension of the utilisation of passive immunity in treatment and it is also a major difficulty in blood transfusion (*see below*).

When investigated in detail quite small molecules can be shown to be antigenic. Thus purified insulin (molecular weight about 6,000) prepared from the pancreas of one animal is antigenic when suitably injected into a different species. Furthermore, very small variations in molecules can cause the production of specific and different antibodies. By coupling certain glucoside and galactoside molecules to proteins Avery and Goebel were able to produce specific antibodies although the antigens differ only in the attachment of *one* H atom and *one* OH group to one Carbon atom. In many instances the action of quite a simple chemical (for instance formaldehyde) can alter the specificity of an antigen but fortunately this is not universally so. Apart from proteins, polysaccharides (*i.e.*, quite large molecules made up by the polymerisation or linking together of glucose and similar small carbohydrate molecules) are antigenic in many animals. This has been closely investigated in the case of dextran (a polymer of glucose alone) where in man molecules with a molecular weight less than about 100,000 are not antigenic whereas polymers with molecular weights over 600,000 certainly can be. Dextran is widely used in medicine where blood for transfusion is not available. The larger molecule material would be valuable in that it remains in the circulation longer but unfortunately it cannot be used owing to its antigenicity.

The various serological types of *Str. pneumoniae* causing pneumococcal pneumonia have been mentioned above. It was quickly appreciated that the organisms when first isolated were surrounded by an individual capsule, that this capsule was related to the specific serological type and that the capsule consists of polysaccharide substance. Curiously enough, the polysaccharide substance itself is antigenic in man and mice but in rabbits the whole organism has to be used although the antibody produced only reacts with the capsular substance.

Blood Groups.

The ABO System.—It was mentioned above that *species specific antibodies* can be prepared by the repeated injection of the blood of one species into another. Apart from induced antibodies there are in humans antibodies quite normally in circulation. These are called *agglutinins* because they agglutinate or clump together corpuscles foreign to them. The whole human race can be divided into four groups named from the agglutinogens (antigens) present in their red corpuscles—A, B, AB, and O. Everybody of group A will have agglutinins against B cells in his or her blood, and everybody of group B agglutinins against A cells. The AB person has neither, and the O person has both agglutinins in his or her serum. More recently it has been appreciated that group A is not homogeneous but can be divided into subgroups A_1 and A_2 and other subdivisions. The recognition of these groups is of course the first step in the selection of blood for transfusion.

The Rh System.—In 1939 arising out of work with Rhesus monkeys it was suddenly appreciated that there was a whole new blood group system (designated the Rh system or rhesus system) and everybody was either Rh-positive or Rh-negative. Mathematical examination of the experimental results led Fisher to state that three allelomorphic (Greek roots: *allelo-* = other, *morph-* = form) pairs of factors were involved and he designated the Rh+ factors C, D, E, the Rh− factors c, d, e. It is important to realise that (1) this system is inherited separately from the ABO group so that one may be Group A Rh+ or Group A Rh−, etc.; (2) both the factors CDE and cde are antigenic although there is a great difference in their respective degrees of antigenicity; for instance, anti-D antibodies develop very readily with a small stimulating dose, anti-c antibodies less readily, and anti-d antibody has not yet been definitely identified; (3) there are *no* circulating antibodies of the Rh system in normal people corresponding to the agglutinins of the ABO system normally present.

Inheritance of Rh Factors.—We inherit some factors from each parent. Thus to take a specific example, a man might be cDE/CDe and his wife cde/cde; thus their children would be either cDE/cde or CDe/cde—in both cases Rh+ born of an Rh− mother. Unfortunately it is possible, indeed very usual, for some of a baby's red cells to obtain access to its mother's circulation and stimulate her to form antibodies to the baby's red corpuscles. In general it is only in the type of situation exampled above (*i.e.*, an Rh+ baby carried by an Rh− mother) that serious consequences arise. As mentioned previously, the D factor is highly antigenic; the mother may have an antibody titre of 1:1,000 or even more and these antibodies leak back across the placenta into the baby's bloodstream causing destruction of the red corpuscles, and at the same time jaundice (yellowness due to accumulation of bile pigments). The diseases produced, *Hydrops foetalis* and *Icterus gravis neonatorum*, and many puzzling facts about them, had been known for a long time but only became explicable with the discovery of the Rh system. Thus first babies are rarely affected and never seriously; the mother has not produced sufficient antibody. Subsequent pregnancies are more and more seriously affected until about the fifth or sixth when the baby may be so seriously affected as to be born dead. But

yet again in some families some of the children are born perfectly healthy, neither jaundiced nor anaemic. To understand this let us imagine a father CDE/cde; he will react as and be called Rh+ but in fact he is heterozygous (Greek roots: *hetero-* = different; *zygo-* = join) meaning his reproductive condition is "mixed". Suppose he marries an Rh− woman cde/cde; half of their children will be CDe/cde and the other half cde/cde. The latter children are Rh− and cannot be affected even if the mother has been sensitised by a previous Rh+ infant.

Antibody Detection.

There are many fascinating technical tricks used for detecting and estimating quantitatively the presence of antibodies. Quantitation is usually done by using serial doubling dilutions of the patient's serum (or unknown serum) in the test and the greatest dilution in which a positive result is detected is recorded as the *titre* (thus 1:256 or 1:10,000, etc.). For some antibodies, particularly antitoxins of therapeutic value, international standards have been laid down and these are available to manufacturers to compare with their own products so that they can mark them as "containing not less than 100,000 i.u./ml", etc., etc.

(1) *Protection.*—The earliest methods assessed the actual protection given to experimental animals. Thus groups of 50 or more animals would be given different amounts of the antitoxin, etc., being assayed and then challenged with a standard amount of toxin of known potency. In some groups all the animals would die, in one group about half and in the other groups all would survive. This method has been replaced as far as possible by methods not using animals as the test system.

(2) *Agglutination.*—Rh antibodies and some antibacterial antibodies cause clumping or agglutination of Rh+ corpuscles (or the bacteria as the case may be) and all that is necessary is to incubate tubes containing serial doubling dilutions of the unknown serum in a standard volume with a standardised suspension at 37° C (98·4° F) and then read the tubes with hand lens or microscope. There may be one doubtful tube but above this dilution the suspension will remain milky and below this dilution the corpuscles (or bacteria) will have clumped together and fallen in a mass to the bottom of the tube so that the liquid is clear.

(3) *"Complement Fixation".*—The above is a valuable technique but in many antigen-antibody reations there is no visible change. In many of these, fortunately, *complement* is used up. Complement is a heat labile protein present in fresh blood and vitally necessary for some antigen-antibody reactions to occur at all. It is a very complex test to describe but systems can be devised where the quantity of complement is sufficient for one reaction only. Thus if there *is* antibody in the unknown serum the complement will be used up and the second reaction (usually a lysis or destruction of red cells) cannot occur. Thus the tubes without antibody go clear bright red, the tubes with antibody remain smoky pink with intact red corpuscles. Again the titre can be read.

(4) *Precipitin Test.*—Another large group of antibodies fortunately produce a precipitate which can be shown by techniques developed by Ochterlony and others. A gel of gelatine, agar or some such material is formed in a shallow sheet; a number of holes are cut vertically into it—one in the centre and a ring at suitable intervals round the outside—usually about six or seven holes in all forming little "wells." The known antigen is placed in the centre well and the unknowns, with a suitable control, are placed in those round the outside. The preparation is kept moist and within a few hours the protein solutions have diffused through the gel and a line of precipitate is produced where antigen and antibody meet. The precipitate is often visible by direct oblique lighting but may need staining with a dye. This is an oversimplified description and there are many difficulties; for instance left too long the precipitate will re-dissolve in excess of antigen. However, the technique is immensely valuable for many applications and can be used quantitatively. Also working with an unknown serum in the centre and a series of known antigens around the outside a great deal of information about the antibodies present can be obtained from one test.

(5) *Immunoelectrophoresis.*—The method can be further extended by utilising *Immunoelectrophoresis.* If we pass an electric current through serum under suitable conditions (say 100 m.a. at 300 v.D.C.), overnight the proteins in the serum separate into zones or bands according to the size of the molecule. Thus separate bands represent the globulins and the albumins. The globulins can be further divided into α, β, and γ globulins. Now if this technique is performed in an agar gel and a narrow trough cut along the length of the direction of passage of current, multiple precipitin bands can then be produced by filling this little trough with potent but dilute antiserum. Curiously this technique has proved of more value for the recognition of unusual protein fractions than for the separation of antibodies but it is primarily an immunologist's technique. In passing we may mention that it is in the γ-fraction of the globulin that the majority of the antibodies occur and it is this fraction, when obtained in bulk from suitable subjects and purified, which is available for use in treatment (*see earlier*).

(6) *Fluorescence.*—Another technique which has recently come to the fore and proved immensely valuable is *immunofluorescence.* Certain dyestuffs fluoresce very brilliantly (i.e., when illuminated with light of short wavelength—either blue or ultra-violet—they give out golden-yellow, orange, or red, etc., light). This is sufficiently brilliant, when a suitably bright source of illumination is available (now the H.P. mercury vapour lamp), and of sufficiently different colour from the tissue auto-fluorescence that it can be applied to thin tissue sections under the microscope. The first technique is to "conjugate" the antibody with the dye (commonly Fluorescein) and remove the excess dye. This is technically complicated and needs care or the antibody loses its potency. However, it is a routine procedure these days. The technique can be used in many ways: for example (1) supposing the antibody is of known specificity it can be used to identify in tissues or to smear the virus, bacterium, fungus, or protozoan against which it is specific; or (2) using known antigens, the conjugated unknown antibody can be identified.

The second technique of very much wider application is the *indirect* or *sandwich technique.* It has the advantage that only one fluorescent antibody need be prepared instead of one for each patient. It is best explained by a specific example. In cases of the anaemia called *pernicious anaemia* there is an antibody circulating in the blood which reacts with the lining cells of the stomach. So to provide a routine test for these antibodies one needs fresh frozen sections of stomach (usually rat stomach). The patients' sera are then applied to these sections, one section per patient and suitable controls. The antibody, if present, attaches itself to the antigen—the stomach cells. Remember this is *human* antibody attaching itself to *rat* cells. The sections are then washed so that the only remaining protein of human origin will be the antibody, if present. Then the reagent required to demonstrate this is an anti-human antiserum to which Fluorescein has been conjugated, an antiserum commercially available and usually from rabbit. Under the microscope a positive result is shown by a striking and beautiful yellow-green fluorescence of the lining cells whereas the muscle and blood vessels, etc., will only show the pale blue and silver auto-fluorescence of all biological tissues.

One very exciting use of these fluorescent techniques is to track down the cells actually manufacturing the antibody, this seems in general to be in cells of the lymphoid series (*see below*).

issues as Antigens.

Most tissues ground up and injected into animals cause the production of specific antibodies; kidney produces specific anti-kidney antibody and so on. A few tissues contain several antigens; for instance with thyroid gland there may be anti-thyroglobulins reacting with the secretory material and also antibodies reacting with the epithelium (the sheets of cells which cover such surfaces as the skin and lining membranes). There are two exceptions to this general rule; fortunately and very importantly the cornea of the eye, the tissue forming the transparent window at the front of the eye, is non-antigenic. Hence any healthy cornea can be grafted into any other human related or not, of the same blood group or not. Second, it has been claimed that the material of heart valves, provided they are completely free of blood and of all other tissues, is non-antigenic. This has led to attempts to transplant pig valves into humans but at present artificial valves of plastic have proved more reliable

An animal does not usually manufacture antibodies to its own tissues. This was recognised and commented upon by Ehrlich ("autotoxicus horrificus"). The mechanism for this has only recently been discovered through experimental grafting of skin into new-born animals. At birth the skin will, in some species, "take" (*i.e.*, survive) even if grafted from an unrelated individual of the same species. Yet if grafted only a few days after birth the graft will not take. During this short period immunologically potent cells (*i.e.*, cells capable of producing antibodies when stimulated) have spread to all parts of the body, it is now believed from the thymus (a hitherto enigmatic structure, largely of lymphoid tissue, found above and in front of the pericardial sac (enclosing the heart) in young animals, in humans practically disappearing by the late teens). These cells are capable of "recognising" all the constituents of the owner's body and yet reacting to almost any protein and many other substances as "foreign."

Just occasionally this mechanism fails and patients develop antibodies against their own tissues. This was first appreciated in regard to a rather uncommon thyroid disorder but every year an immune aspect to the development of some other disease is brought to light (as, for instance, in *pernicious anaemia* mentioned above). These anti-tissue antibodies are detected by the fluorescent methods discussed above but their role in the production of disease is as yet poorly understood, and the reason for the breakdown in the protective mechanism even less well.

Depression of the Immune Response.

It is well known that starvation, malnutrition, old age, and some disease states lower the ability to produce an immune response. More recently, some drugs and also full body irradiation (with X-rays) have been used to produce deliberately a reduction in immune response particularly when grafting kidneys or bone marrow. The X-rays cause an almost total disappearance of circulating lymphocytes (one of the several types of white cell in the blood, numbering in humans about 1,500 per cubic mm.) Of course during the period of lymphocyte depression the patient is unable to respond to infection of any sort so that immense care has to be taken to completely isolate the patient, sterilise the air he breathes and everything with which he comes in contact. If the lymphocytes are not sufficiently depressed they will react to the grafted tissue, spread into it and produce changes which prevent it surviving. In animals it has been shown that, with bone marrow transplants, the *graft* can reject the *host*. The animal ceases to put on weight and eventually dies. This may be a bar to the more widespread application of bone marrow transplantation in humans.

Hypersensitivity.

Animals, particularly guinea pigs, sensitised with protein such as horse serum and given, after a suitable interval, another very small dose intravenously go into a state of shock and frequently die—a reaction called *anaphylaxis*. A similar reaction, fortunately usually less dramatic and readily treated, occasionally occurs in humans. Depending on the traits of the person concerned the attack may take the form of severe asthma or of severe *urticaria* (large fluid-filled "blisters," painful and itching, occuring in the skin of the whole body). This is called "serum sickness" and is a major difficulty in the application of the methods of passive immunity.

Similarly some people become readily sensitised to other foreign materials, inhaled or injected. Among such substances may be mentioned grass and tree pollens (asthma and hay fever), flour and pollens such as *Primula obconica* (dermatitis) and less commonly foodstuffs such as egg protein (producing immediate vomiting probably followed by diarrhoea). However, this is the field of the allergist not the immunologist and so will not be further discussed.

Delayed Sensitivity and Transferable Sensitivity.

With some immune reactions no detectable antibody appears in the blood. For instance, a skin graft from an unrelated animal of the same species survives perhaps for 7–10 days and then dies and is rejected. This seems clearly an immune response and yet there are apparently no circulating antibodies. From fluorescence microscopy it now seems clear that lymphocytes do respond to this stimulus but only locally. However, the induced sensivitity is retained, a second graft is rejected more quickly, and a third graft even more quickly. Furthermore, this sensitivity can be transferred by transferring the lymphocytes. This has to be done with highly in-bred strains of animals but if lymphocytes collected from the thoracic duct of a rat that has rejected a graft are transferred to another closely related rat, the second rat will reject a skin graft as quickly as if it had been previously sensitised by a graft itself. Some other sensitivity reactions have been similarly transferred just by transferring lymphocytes (for instance, *allergic encephalomyelitis* in rabbits).

DRUGS ACTING ON THE BRAIN.

Drugs which act primarily on the brain can be classified into four main groups:

(1) *Depressant* (Anaesthetics and sedatives)	Ether Barbiturates
(2) *Stimulant*	Caffeine Amphetamine (Benzedrine)
(3) *Tranquillisers*	Chloropromazine (Largactil) Reserpine
(4) *Hallucinogenic*	Mescaline d-Lysergic acid diethylamide (LSD 25)
(5) *Miscellaneous* Analgesic Anti-convulsant	Morphine, Heroin Trimethadione

There are those which depress the central nervous system and cause loss of consciousness, such as anaesthetics and sedative drugs, and those which stimulate the brain, retarding sleep and lethargy and causing increased wakefulness; then there are drugs which have a depressant action on certain types of behaviour such as the hyperactivity which is present in some psychiatric conditions, but without affecting consciousness, *i.e.*, tranquillisers. Finally, we have a group of drugs which mimic symptoms normally associated with psychiatric disturbances, producing sensory illusions and hallucinations, the hallucinogenic drugs.

These are not, of course, the only types of drugs which have actions on the brain; there are also analgesic or pain-relieving drugs such as morphine

and heroin, anti-convulsant drugs which are used in the treatment of epilepsy and which are not simply depressant, and many others used for specific purposes such as the relief of tremor and rigidity, the prevention of vomiting, temperature lowering, etc. In addition, there are some newer types of drugs which appear to act specifically on certain mental states. Examples here are the "antidepressant" drugs which do not simply produce increased alertness but elevate mood and relieve psychiatric depression.

Thus, it can be seen that the classification of drugs acting on the brain is at present mainly based on their clinical effects rather than on their pharmacological mechanisms of action. This is largely because most of these drugs have been developed to treat certain clinical conditions and their precise mechanisms of action are not yet fully understood. In addition, it must be mentioned that many drugs do not have a single action but often multiple actions. Thus, some barbiturates are not only sedatives but can be used as anti-convulsants and the phenothiazine tranquillisers can be used as anti-emetics. Furthermore, many drugs which act on the brain also have effects in other parts of the body. It is therefore sometimes difficult to distinguish between the effects produced by a drug due to its direct action on the central nervous system and those which are produced indirectly.

Investigating the Brain.

The brain is a very complex organ, perhaps the most complex in the body, and the study of its function has been largely neglected until recent years, mainly because of the lack of suitable techniques for investigation. The present techniques for researching into the functioning of the central nervous system have come from different fields. The brain is made up of many nerve cells, the human brain containing more than ten thousand million. One way in which we can study the brain is to examine its structure or anatomy in order to determine how the nerves from the various parts of the body are connected to it and also follow connections within the brain itself. However, this does not help us to understand how it functions. Another way is to look at the chemical constitution of the brain and especially to see how chemical changes may be associated with changes in function. The use of biochemical techniques in this way is becoming of increasing importance, especially in studying some psychiatric disturbances. A third method is to study the electrical properties of nerve cells. It has been found that all nerve cells are electrically excitable and when stimulated they produce a characteristic change in electrical potential which is called the *action potential*. This travels along the nerve and is believed to be responsible for the conduction of messages from the brain to other parts of the body and also from the sense organs to the brain. In the brain where we have many thousands of nerve cells aggregated together, they not only produce individual action potentials, but other electrical patterns which appear as waves and can be recorded from the surface of the brain (the cerebral cortex) or from the scalp. These "brain waves" are normally recorded on a moving chart or strip of paper and form a graph: the electroencephalogram or EEG. Studies of the EEG and other electrophysiological potentials of the brain have yielded important information about the actions of some of the drugs mentioned above.

One characteristic feature of the EEG is that it shows pronounced changes during the transition from sleep to wakefulness and *vice versa* and the patterns which are recorded in different states of wakefulness and sleep are well-defined. This is true not only in man but also for many species of animals. While the electrical patterns recorded from the cerebral cortex reflect different levels of somnolence or vigilance, it has been found that the control of sleep and wakefulness is exerted by a structure known as the *reticular formation of the brain stem* lying deep within the brain. This structure produces widespread effects on the higher centres of the brain and normally provides an influence which keeps the rest of the brain awake. Removal of this influence results in sleep or loss of consciousness. The reticular formati is itself influenced by other regions of the bra particularly the sensory pathways convey information from the sense organs. Thus, t pulses in sensory nerves corresponding to parti lar sensory stimuli are conveyed not only to th region of the brain (the sensory area of the cerebr cortex) responsible for their perception but a into the reticular formation where they produ a change in the level of activity and, ultimate increased alertness. This influence from t sensory pathway is known as the *collateral sens input*. Changes in the level of activity in t reticular formation may also occur spontaneou and in response to other influences, *e.g.*, humor blood pressure, drugs, etc. The reticular form tion is concerned with other functions in t central nervous system, for example, the cont of respiration and blood pressure, and it has influences on spinal reflexes.

Drugs, Wakefulness, and Sleep.

There are two groups of drugs (*see above*) wh produce profound changes in levels of wakefuln and sleep. Since the brain stem reticular form tion is the region responsible for the maintenan of wakefulness, it would seem likely that th drugs might have actions on this structure and th has, in fact, been found to be the case for ma drugs which depress wakefulness and others wh stimulate it. Thus, barbiturates such as pent barbitone and pentothal, which are used to indu anæsthesia, produce their depressant effects direct action on the mechanisms located in t reticular formation which are concerned with t maintenance of wakefulness. It seems likely th these drugs block the conduction of nerve impuls in the reticular formation and so prevent the lat from maintaining its influence on other hig brain structures, particularly the cerebral cort Sleep or loss of consciousness therefore ensues, t degree of the effect depending upon the poten of the substance and the amount which has be given. Thus, some barbiturate drugs given large enough quantities cause loss of consciou ness and a loss of responses to sensory stimu including pain, therefore producing anæsthes Other barbiturates cause only sedation and c be used to relieve insomnia. The central stim lant drugs, on the other hand, produce oppos effects and the increased wakefulness and alertn which they induce appears to be related to a fac tatory action on the reticular formation of t brain stem. This action is probably related an increase in the spontaneous activity of t neurones (nerve cells) in the reticular formati which has been observed following administrati of amphetamine. Similar effects have be observed with a number of centrally stimulati drugs and so in all probability responsible the more mild stimulation produced by caffei These two groups of drugs therefore, the cent depressants and central stimulants which ha opposite effects on behaviour, also have oppos actions on the nervous mechanisms concerned wi sleep and the maintenance of wakefulness. W conclude that these actions are probably respo sible for their effects on levels of consciousness.

Tranquillisers.

The drugs of groups (3) and (4) (*see above*) not produce appreciable changes in consci states, but appear to have more subtle actions brain function. For this reason, therefore, th are rather more interesting. There are now large number of drugs which have a tranquillis action on the brain. Some of the most pot of these are derivatives of phenothiazine and o of these, chlorpromazine (or Largactil), is the old of this group of drugs and is still extensively us Administration of this drug in both animals a man produces a state of unresponsiveness a non-reactivity and it is particularly useful in t treatment of certain mental disorders, especia where hyperactivity is prevalent, *i.e.*, in ma states. Investigations of the actions of the phen thiazine tranquillisers using electrophysiologi techniques have shown that they act at the le of the reticular formation of the brain stem but

ot directly depress the arousal mechanisms as o the barbiturates. Their depressant action ppears to be more closely linked to the collateral fluences from sensory pathways entering the eticular formation. Thus, chlorpromazine deresses sensory influences on arousal mechanism ithout preventing the conduction of impulses rough the main sensory pathways and also ithout depressing the arousal mechanisms located the reticular formation. This drug therefore as a selective depressant action related to the ollateral sensory input to the arousal system. uch an action can also explain many of the other ffects produced by the drug, *e.g.*, effects on temerature regulation, anti-vomiting action, potenation of anæsthesia, etc.

SD.

Of the hallucinogenic drugs, the synthetic subance d-lysergic acid diethylamide (LSD 25), hich was discovered accidentally, has been the ost widely studied of this group of compounds ecause of its extreme potency. A dose as small 50 micrograms or 50 millionth parts of a gram an cause marked disturbances of mental function man. The substance has little or no therapeutic alue, but since the symptoms which it produces osely resemble those observed in naturally ccuring mental disorders, it provides a means for aking a model of these diseases. By studying he mechanism of action of this drug on the brain e may learn more about the kind of mechanisms hich may be responsible for such naturally occurng disorders as schizophrenia. Electrophysioogical experiments with LSD 25 have shown that s site of action in the brain is closely related to hat of the tranquillisers, *i.e.*, it has effects related o sensory influences on the reticular formation. owever, the action of LSD 25 is opposite to that f chlorpromazine and is facilitatory instead of epressant. The effect of a given sensory stimulus n the level of wakefulness is therefore enhanced y administration of LSD 25. This means that ehavioural effects observed with this drug are ery dependent upon the degree of sensory stimlation and therefore upon environmental condions. This factor is important in observations f the effects of drugs in which changes in beaviour are used to define their actions and illusrates the need for careful control of environental conditions in such experiments. The ction of LSD 25 in facilitating the influence of ensory stimuli on the reticular formation of the rain stem can easily explain the effects of this rug on sensory experience if we remember that he brain stem controls the level of vigilance at he cerebral cortex.

Other experiments with tranquillisers and hallunogenic drugs have been carried out in animals sing conditioning techniques and have shown hat the actions of both of these groups of drugs re very closely linked to the neurophysiological echanisms in the central nervous system which re concerned with the way in which the brain andles sensory information—with the filtering nd integration of such information. These xperiments have also shown that while chlorromazine potentiates the process of habituation a which the organism learns not to respond to a epeated stimulus of low biological significance, SD 25 acts in the opposite manner, retarding the rocess of habituation and increasing the apparent significance " of such stimuli. These observaons are again consistent with the observed effects f these drugs in man. However, very little is as et known about the detailed mechanisms inolved in these processes and this places a limitaon on the degree of precision with which the ffects of these drugs can be defined in such terms.

nvestigation of Individual Nerve Cells.

A recent further development in the analysis of rugs on the brain consists of recording the electrial activity of the individual cells of the brain ith micro-electrodes and applying drugs directly o the surface of the nerve cell. This is done by neans of small glass pipettes fused into four or ve barrels, which are drawn out to a very fine ip. One barrel is used for recording the action potential (*see* **F68(1)**) of the cell while the others contain aqueous solutions of the substances to be tested. By passing a small electric current through the appropriate barrel of the pipette, ions of the active substance are ejected from the tip in the vicinity of the cell. If the cell is sensitive to this particular substance, then a change in its activity will be observed. This method, which is known as " iontophoretic " application, is enabling the actions of drugs to be studied in more detail in order to determine whether they are producing effects by direct actions on the nerve cells of the brain or by indirect actions. In addition, the effects of various substances which are thought to be chemical transmitters in the brain, *i.e.*, are responsible for the conduction of nerve impulses from one cell to another, can be examined by this technique. Substances in the latter category are acetylcholine, noradrenaline and 5-hydroxytryptamine, all of which naturally occur in the brain. Furthermore, acetylcholine is the transmitter substance at the neuromuscular junction, *i.e.*, the junction between motor nerves and muscle fibres in the body and both acetylcholine and adrenaline are concerned with transmission at certain ganglia (nerve centres).

In studies of the pharmacological properties of neurones in the brain stem reticular formation, using the method of iontophoresis, it has been found that all three of these substances are effective in modifying the activity of certain cells, and that each substance can have either an excitatory or depressant effect. Thus, there are some cells whose activity is increased by application of acetylcholine, others whose activity is depressed, and some which are unaffected by iontophoretic application of this substance, and the same is true for noradrenaline and 5-hydroxytryptamine although the proportions excited, depressed, or unaffected vary. Furthermore, it has been found that when the actions of all three substances are tested on the same neurone, mixed effects can occur. Thus, some cells may be excited by all three substances, others depressed by all three; some excited by one and inhibited by the other two, and others excited by two and inhibited by one and various combinations of excitation, inhibition, or lack of effect, occur. The situation is therefore somewhat complex and it appears that there is a considerable variety of pharmacological properties in the neurones of the brain stem reticular formation. At this stage it is not possible to relate these properties of the neurones to their functional rôle.

Some Preliminary Results.

This work is still in its infancy and while it is not yet possible to explain the actions of drugs fully in terms of their effects on individual neurones, some of the preliminary findings give tentative indications. For example, when the effects of barbiturate drugs were examined iontophoretically on single neurones, it was found that depression of activity almost always occurred, although the sensitivity of the neurones to the substances appeared to vary. Further studies of this kind should yield important information about the nature of the depressant action of the barbiturates on the neurones of the brain stem reticular formation. Similarly, it has been found that while chlorpromazine has a depressant action on many neurones in this region, it seems to affect only neurones which are also affected by application of noradrenaline. Furthermore, chlorpromazine antagonises the excitatory actions of noradrenaline but not its inhibitory actions; nor does it modify the actions of acetylcholine or 5-hydroxytryptamine. This drug may therefore be acting as a selective antagonist at sites in the brain where noradrenaline is an excitatory transmitter substance and if this proved to be true, it provides an important clue to its mode of action in the brain.

It can be seen that electrophysiological investigation of drug action in the central nervous system can provide useful information on their sites and mode of action. Investigations at the level of the single cell with local application of drugs will carry this a stage further and provide us with information of a more precise nature.

PART IV. INDEX AND GLOSSARY

Abdomen. The part of the body below the chest and above the thighs.

Abortion. The termination of pregnancy, from whatever cause, before the child is capable of independent existence, 56 (2).

Abortus fever. An infectious disease known as undulant fever, 15 (1).

Abrasion. Any injury which rubs off the surface skin.

Abscess. A collection of pus enclosed anywhere in the body.

Acidity. *See under* Peptic ulcer, 36 (1).

Acne, 53 (2).

Acromegaly. A state of excessive growth of the body caused by overaction of the pituitary gland in the base of the brain, 44 (1).

ACTH. An abbreviation for adreno-corticotrophic-hormone, a drug related to cortisone.

Actinomycosis, 15 (2).

Acute nephritis, 45 (1).

Addiction to drugs. *See* Drug abuse, 22.

Addison's disease, 44 (1).

Adenoids, 32 (1).

Adhesions. An occasional cause of pain after operations when abraded areas adhere to each other.

Adreno-genital syndrome, 44 (1).

Air we breathe, 4 (1).

Agranulocytosis, 26(1).

Alcoholics Anonymous, 6 (2).

Allergy. Abnormal sensitivity to any substance which does not affect normal people.

Alopecia, 52 (2).

Amenorrhœa, 56 (2).

Amnesia. Loss of memory, *see under* Neurosis, 51 (1).

Amœbæ, 8 (1).

Amœbic dysentery, 17 (2).

Amphetamine, 23 (2), 67 (2).

Amyotrophic lateral sclerosis, 49 (1).

Anæmias, 24–25.

Anæsthetic. Any drug used by surgeons to remove pain during an operation.

Aneurism, 30 (2), 46 (2).

Angina pectoris, 28 (2).

Angio-neurotic œdema, 49 (1).

Ankylosis. Partial or complete fixation of a joint as after some types of arthritis. In other cases deliberately produced by surgery.

Ankylostomiasis, 16 (2).

Anorexia. Loss of appetite.

Anthrax, 15 (1), 9 (1), 4 (2).

Antibiotics are drugs which act directly against the organism causing the illness by interfering with its growth or some other aspect of its living mechanisms. Of all drugs which are used against bacteria, antibiotics do least harm to the patient's own tissues; some do have unwanted side-effect, but many have none at all. *See* 4, 9, 22.

Antihistamine drugs, 4 (2), 5 (1).

Antiseptics, 8 (2).

Antibodies, 63 (2).

Antigens, 63 (2).

Anxiety neurosis, 51 (1).

Aortic diseases, 30 (2).

Aphasia, 47 (2).

Aplastic anæmia, 25 (1).

Appendicitis, 37 (1).

Arteriography, 47 (1).

Arthritis, 54 (2).

Artificial respiration (kiss of life), 21 (1).

Asphyxia, 20 (2).

Aspirin and "upset stomach", 5 (1), 23 (1), 36(2).

Asthma, 32 (1).

Atheroma or Atherosclerosis, 30 (1).

Athlete's foot, 8 (1), 15 (2).

Auscultation. The method used by a doctor wh he listens for signs of disease inside the body means of a stethoscope.

Autonomic Nervous System, 46 (2).

Backache. A symptom which may be caused many different diseases—sometimes disease the vertebræ themselves, sometimes strain the ligaments, and sometimes inflammation spasm of the surrounding muscles. "Lu bago" is usually due to inflammation of muscles in the small of the back. Backa from purely local causes may be treated t porarily by applying heat in the form o kaolin poultice or a rubber hot-water bottle taking two aspirin tablets a day. On the ot hand, many cases of backache are due to dis elsewhere. The most important thing is to out the cause, and therefore a doctor should consulted.

Bacteria, 7 (1). **Bacterial diseases,** 12–15.

Bacteriophage, 7 (2).

Baldness, 52 (2).

Barber's rash, 53 (2).

Barbiturates, 23 (2), 67 (2).

Bell's palsy, 50 (1).

Benzedrine. The proprietary name of a d known as amphetamine. *See* 23 (2), 67 (2).

Beri-beri, 42 (2).

Bilharzia, 18 (2), 16 (1).

Birth control, 57.

Blackwater fever, 17 (2).

Bladder. *See under* Urinary diseases, 44 (2).

Bleeding diseases, 26 (1).

Blepharitis, 55 (1).

Blood, function of the, 24.

Blood, diseases of the, 24.

Blood Groups. Human blood plasma conta factors which clump, or agglutinate, the cells of some other people's blood. The m blood groups are called A, B, AB, and O. plasma of group A blood contains an ant factor and *vice versa*, so that people of gro A and B cannot accept each other's blo Group AB contains neither anti-A not ant factor and people with this group can theref receive transfusions from both but can give neither. Group O contains both anti-A anti-B, and can therefore receive blood from group O but can donate blood to all grou It is important that transfused cells should be agglutinated by the factors in the recipie plasma. Apart from the so-called ABO syst there are several other blood groupings, on which is mentioned under Rhesus Factor. *also* 65 (2).

Blood poisoning (septicæmia), 14 (2).

Blood-pressure, 29.

Blood-vessels, diseases of the, 30.

Blue babies, 5 (2).

Botulism, 14 (1).

Brain. *See under* Nervous system, 46. Phys injuries, 19. Drug effects, 68.

Brain abscess, 47 (1).

Brain tumour, 47 (1).

Breasts, 55 (2).

Bronchial asthma 32 (1)

Bronchiectasis, 32 (1).

Bronchitis, 31(2).

Bruises and abrasions, 19 (2).

Bürger's disease, 31 (1).

Burns and scalds, 21 (2).

Cachexia. Extreme wasting due to disease.
Caesarean operation. When the abdomen has to be opened to remove the child, named after Julius Cæsar, who is said to have been born in this way.
Caisson disease, 31 (1).
Cancer of the breast, 55 (2).
Cancer of the cervix, 56 (1).
Cancer of the colon, 37 (2).
Cancer of the lung, 33 (2), 34 (1).
Cancer of the œsophagus, 36 (1).
Cancer of the rectum, 37 (2).
Cancer of the stomach, 37 (1).
Cancer test (cervical smear), 56 (1).
Carbohydrates. The scientific name for sugars, starches, and cellulose, 34 (2), 40 (1).
Carbon monoxide poisoning, 21 (1).
Carbuncle. A large boil.
Cardiac neurosis, 27 (1).
Cataract, 55 (1).
Chadwick, Sir Edwin (1800–90). English social reformer, 6.
Chancroid, 16 (1).
Change of life, 56 (2).
Chickenpox, 10 (1).
Chilblains, 53 (1).
Chill. This is not a proper medical word, but refers to the symptoms that occur when one first becomes infected with any germs which cause fever. When such germs enter the body, all the defending processes are mobilised and speeded up. The white cells in the blood increase in number, and the amount of energy used is greater than normal, causing the temperature to rise. This rise in temperature increases the ability of the body to fight back, and, in order to retain heat within the body, the blood-vessels in the skin contract so that less heat is lost by radiation. This makes the skin cold and pale. What is ordinarily called a chill is merely an infection by the germs causing cold and influenza. But a chill may be the preliminary to almost any infectious disease, such as measles, mumps, scarlet fever, pneumonia, and so on. The best treatment when the temperature is raised is to go to bed with as much warmth as possible. Hot drinks and hot-water bottles are helpful. *See* Colds, 10 (2).
Cholecystitis, 38 (2).
Cholelithiasis, 38 (2).
Cholera, 15 (1).
Cholesterol, 30 (2).
Chorea (St. Vitus' Dance), 48 (2).
Chronic. A chronic disease is one which is prolonged and relatively mild, as opposed to an acute one which is short and severe.
Chronic nephritis, 45 (1).
Cilia, 31 (2).
Cirrhosis of the liver, 39 (1).
Claustrophobia. A psychological symptom, which causes the individual to be afraid of enclosed spaces. *See under* Obsessional neurosis, 51 (2).
Cocaine, 23 (2).
Coccyx. The end of the spinal column.
Cold sore. *See* Herpes labialis, 49 (2).

Orthopædics. A branch of medicine dealing with the surgery of bones and joints.
steoarthritis, 54 (2).
steomalacia, 42 (1).
Osteomyelitis. An inflammatory disease of bone caused by infection with the streptococcus or staphylococcus. The germ is carried by the blood, but the part where it settles depends on local weakness or such factors as blows and injuries. The first sign is severe pain in the infected bone and fever. Usually the site affected is in the long bones of the arm or leg. Later, a chronic state may develop in which a small sinus, or hole in the limb, discharges large amounts of pus which comes from the inside of the bone. Operation may be necessary, but if caught in an early stage, the disease may be treated with penicillin or sulphonamide drugs. The main danger of osteomyelitis is that absorption of the bacterial poisons into the system leads to damage to the other organs of the body.

Psychosis, 50.
Psychosomatic diseases. Psychosomatic diseases are those physical ailments due to emotional causes. They include such complaints as high blood-pressure, gastric ulcer, certain skin diseases, and certain glandular diseases (*e.g.*, exophthalmic goitre). Most physicians nowadays believe that all diseases may show a greater or less degree of emotional causation; that physical and mental factors are both present in all illness. Even in psychosomatic illnesses, heredity and other factors play a large part. Briefly, the main cause of these diseases is worry. The importance of this lies in the fact that they cannot be cured without dealing with the fundamental cause. *See also* **New Views on Medicine**, 3 (2). Individual illnesses will be found under their names.

Rhesus Factor. Apart from the ABO blood group system (*see* **Blood Groups**) there is another blood group system (designated the Rh-system or Rhesus system). Everybody is either Rh-positive or Rh-negative. Three positive factors (denoted C, D, E) and three negative factors (denoted c, d, e) are involved. This system of blood factors is inherited

separately from the ABO group, so that one may be A Rh+ or A Rh−, etc. Both the positive and the negative factors are antigenic, i.e., if introduced into other blood they will stimulate the production of substances which act in some way against the cells introduced. We inherit some factors from each parent and it may occur that a Rh+ baby is born of a Rh− mother. In this case some of the baby's blood may, and often does, obtain access to the mother's circulation and stimulate her to form substances harmful to the baby's red corpuscles. If these leak back to the baby through the placenta some of the baby's red corpuscles may be adversely affected. This does not usually occur with the first baby, but may become increasingly serious with following pregnancies. *See* 65 (2).

Rodent ulcer, 54 (1).
Rods and Cones are cells in the retina of the eye which convert light into nervous impulses which can be interpreted by the brain. In man the cones are associated with colour vision and used during daylight. The rods are concerned with twilight vision and do not give rise to the sensation of colour. It is probable that there are three types of cones responding to red, green, and violet, other colours being a combination of these three. Rods contain a pigment, visual purple, which is sensitive to light. Vitamin A is necessary for the production of this substance. The changes produced by light on the visual purple initiate a nerve impulse but the exact mechanism is unknown.

HUMAN RELATIONS

r this section we have tried to give the reader an understanding of modern society and of the forces at motivate behaviour so that he can interpret what is going on around him and in his own mind. n effort has also been made to provide that help which understanding alone can give not only in the orking out of one's own problems but in extending tolerance towards the shortcomings of others.

The section is in three parts:

I. The Self (i.e., the individual and his development and the way he meets the problems of life in the process of growing up).

II. Society (i.e., our relationships with other people from the family to the larger social groups and the problems created by changing social patterns).

III. Work (i.e., all the many factors that affect the worker in an industrial society).

These categories overlap to some extent since we are not isolated individuals but involved with eople from the earliest days, and work is an integral part of everyone's life, so each part flows into the ext, occasionally making a little repetition inevitable.

Before we enter this field of human relations, let us remember the words of that great teacher and riter, R. H. Tawney: " Everyone, whether he intends it or not, adopts some attitude to the world of uman beings in which his lot is cast; and, as that attitude is, so in large measure will be both his ersonal happiness and his utility to his fellows. It may be one of sympathy and co-operation, or of ntagonism and suspicion."

INTRODUCTION.

All societies have had their problems and their imes of crisis and modern society is no exception. What is special about our problems is that they re of an entirely different nature from those which faced our forefathers. For them, as over ast areas of the earth even today, the main azards came from an untamed natural environment in which plagues were rampant and malnutrition the rule, in which crops and livestock could e ravaged by adverse weather or disease, bringng starvation and death just as surely as the lagues afflicting man himself. This is still the tate of affairs in many of the technically underleveloped countries of the world where epidemic iseases, chronic infections such as malaria and uberculosis, hunger, poverty, and malnutrition till need immediate action. To improve the uman environment calls for efforts by the ommunity as a whole which these poorer counries are, as yet, incapable of making by themelves, for their people have neither the necessary nowledge, wealth, nor organisation to do so, and, most difficult of all, they need to change longstablished habits and attitudes.

The peoples of the Western countries have so modified their environment that they have succeeded in adding many years to their average expectation of life, yet it is not so long ago that they had to face similar problems. For example, it is little more than a hundred years ago (1848), when the appalling living conditions resulting from the industrial revolution threatened to spread disease throughout Britain, that the first public health measures were taken to deal with the feared cholera and smallpox epidemics which were then prevalent. In Ireland, failure of the potato crop led to the great famine of the 1840s when a million people died of starvation and a million and a quarter were forced to emigrate. During the influenza epidemic which followed the First World War more people died in a single year than were killed on all the fronts in four years of devastating war. During the last 50 years new discoveries and increased medical skill have combined to reduce the death rate of children in Britain in the first year of their lives from 120 per thousand to 22 per thousand (boys) and from 98 thousand to 22 per thousand (girls), so that a baby boy may now expect to live to 68 years and a girl to 74. By a process which began gradually about a hundred years ago and accelerated in recent times until it has become an explosion, our circumstances have radically changed as technology has advanced and along with the truly wonderful scientific achievements of our civilisation have come new and unheralded dangers. We are living largely in a synthetic environment created by our own technology and our most serious problems today are caused not by nature but by ourselves. This is perhaps a depressing fact, but it is also a hopeful one: for we are now at little risk from the physical world around us and it might be thought that the minds which created the new environment are surely capable of solving the problems which come in its wake.

Unfortunately the situation is not quite so simple because, though we know a good deal about the physical universe and how to bring it under control, we know rather less about ourselves and what information is available does not suggest that human problems are as easy to solve as technical ones. Most of us are able to handle things with some measure of efficiency, but we are likely to be much less skilled when it comes to human relationships and, in the long run, even things become tied up with personal emotions. Thus there are not *two* sets of problems, the one concerned with science and technology and the other with mental life, because science and technology *in themselves* create no problems at all—there is really only one problem and that is the uses to which we put our knowledge. Man uses his reason to find out about the physical universe but all too often what he does with his discoveries is determined not by reason but by false beliefs, old traditions, and emotional prejudice.

Among the major problems in the world today are racial and national hatred, undernourishment, over-population, disease in impoverished countries, the threat of nuclear war, failure to adjust to change, superstition, illiteracy and poor educational standards. Most of the causes of these are already known and in many cases the remedies are not only known but capable of being put into practice immediately. What stops them from being effectively dealt with is not lack of knowledge but the fact that we are unable to understand or control ourselves; the problems are not outside but inside man—his stupidity, greed, aggressiveness, suspicions and prejudices. These are the concern of the psychologist, because psychology is the scientific study of human behaviour, emotions, and thoughts. In the pages that follow we shall be dealing mainly with those aspects of the subject which are most relevant to the individual citizen in the Western world today but it is hoped that the reader will gain some insight into the forces which motivate all men irrespective of politics, race, or creed.

Adjusting to Inevitable Change.

Broadly speaking, the problems of the West are those of the Welfare State or what has been described as the Affluent Society (the two are not quite the same because, though a welfare state may be affluent, an affluent society like America is certainly not a welfare state). Along with very real benefits such as comparative economic security, improved material well-being, freedom from many of the killing diseases which once plagued us, greater social mobility, and better opportunities for higher education, have come other features which cannot be cured by more affluence. Many people are bored, rebellious, perplexed, and downright unhappy, and some would ascribe this to the 'spiritual sickness of our time' brought about by the loss of traditional values. Perhaps they are right. The only trouble about this analysis is that it is not a very helpful approach because traditional values c not be brought back by legislation, nor is it sirable that they should be brought back at Our real problem is that we have failed to adj to a rapidly-changing technological environme which demands a new set of values and fr attitudes. More than a century and a half ag famous philosopher wrote that "man, insofar he acts to change his environment, acts to cha himself," and herein lies our failure; we h created a new environment but have failed make new adjustments to it though the essence normality is the ability to see and react app priately to life as it is. The authoritarian fam has gone, woman's place in relation to home a work has changed, traditional attitudes in dustry are dying, and the gulf in understand between parents and children has increased cause the pre-war world is not the world of tod All these issues will be discussed here.

I. THE SELF

1. THE FOUNDATIONS.

What is Personality?

Personality may be defined as that arrangement of traits which are relatively consistent and enduring attributes of an individual's behaviour. Thus if one man is aggressive in any and every situation and another gentle and thoughtful towards everyone he meets, then we are entitled to assume that these are fundamental and relatively fixed aspects of their personalities.

On the other hand, it is easy to see that whilst some aspects of behaviour are comparatively stable, people's actions are also variable—they may be shy in one set of circumstances and not in another, dominating within one group and submissive elsewhere. This is because these traits are not something *in* the individual, but are simply a response to the social circumstances he is facing at the moment. In more technical terms, they are not a function of his personality but rather a function of the role he is playing as a member of a group facing a specific situation.

So it often happens that we attribute certain characteristics of a person to his innate traits when, in fact, they only appear to be fixed because we always meet him in the same social surroundings. For example, a supervisor in a factory who finds that one of his workers is always resentful is liable to suppose that he is just resentful by nature, whereas, if he saw the man at home he might be surprised to discover that his family and neighbours regard him as kindly and generous to a fault. The reason is, of course, that the worker is resentful in response to the factory situation which, being the kind of person he is, he finds frustrating because it does not permit free expression to his real abilities. Thus what might be described as the 'core' personality is rigid in structure and resists change, whilst the more superficial aspects of personality, of which the above is an instance, change very rapidly as the individual moves from one group to another, and these aspects are described as relating to the 'peripheral', 'public', or 'social' personality. The practical significance of this distinction will be seen later, but it is obvious that if we are dealing with a social problem such as juvenile delinquency it is absolutely necessary to know whether, in a given case, we are faced with an attitude which is firmly ingrained in the youth or whether he is simply responding to a frustrating environment.

Some aspects of personality are therefore relatively fixed whilst others merely reflect responses to a particular environment, but the two cannot be entirely separated because most of the time people tend to respond, not to the environment as it really is but *to the environment as they interpret it* and this naturally depends upon the nature of their core personality. In the example of the worker quoted above, it is obvious that he was suspicious, not merely because of the objective situation (which of course first aroused his suspicions) but because he was the sort of person who might be expected to feel that way in those circumstances. Perhaps his innate intelligence and the fact that he had been brought up with the ambition to better himself made the situation m intolerable to him than to his mates (though some factories things may be so bad that nea everyone feels dissatisfied). But this does alter the fact that a change to a more satisfy job would change the behaviour of this particu man, whilst, in other cases, suspiciousness may an ingrained trait which appears in any situati

How is Personality Fashioned?

Where, then, do these fixed traits come fro Broadly speaking, they arise from three disti but interacting sources: temperament, the chi rearing patterns of the first five or six years of l and the culture in which the individual is brou up. Temperament is what we inherit, and chi rearing patterns are based on the way in wh the parents attempt to pass on the culture to wh they and their children belong. The family, it been said, is the personality-factory of soci which attempts with greater or lesser success inculcate the ideals of a particular group i each new generation. To use another metaph we come into the world as an undifferentiat lump of clay which nevertheless has its o particular properties, the family is the potter, a culture supplies the design. If our society val conquest, we shall be brought up to admire a try to emulate war-like men; if it measures s cess in terms of money we shall see acquisitiven and wealth as our goal; and, in a caste socie we must learn to behave in all ways according the position into which we are born. This id pattern is the *basic personality structure* and presents those aspects of personality which d tinguish the members of one cultural group fr another and defines what is considered 'normal' in a given society. The variations this common theme which differentiate member of the group from any other mem making him, to some extent, a unique individu and what is described as 'character'. Since t interplay between these various factors is ve subtle, it is necessary to discuss them in m detail.

Temperament.

Just a century ago the Austrian monk Greg Mendel was able to show that the physi characteristics of plants are passed on from o generation to the next according to certain defin laws (*see* Section F, Part II). It is known th such factors as body-build, hair and eye colo height, and the rest are inherited in this way, a there are a few diseases (probably not more th can be counted on the fingers of one hand) such haemophilia, which are also known to be hered ary. But when it comes to mental traits, we s on much less secure ground, largely because it difficult to distinguish between what has been herited and what has been learnt. Nearly psychologists believe that if a son is fussy a punctilious like his father this is because he h been taught to behave in this way or has learn it by imitation, and whilst many psychiatri (*i.e.*, physicians who specialise in treating men

orders) believe that a *tendency* to certain forms insanity is inherited, few would accept that this true of the minor forms of neurosis. It is own for certain that general intelligence is demined at the moment of conception, and quite ely that the traits collectively described as mperament ' are largely inherited because they m to be correlated with body-build. The short cky individual with a tendency to run to fat is ually cheerful and outgoing—one of those described by Shakespeare when he referred to " men at are fat, sleek-headed men and such as sleep ights " and compared them to Cassius with his ean and hungry look " who " thinks too much—ch men are dangerous ". The former type of dy-build is the ' pyknic ' and his temperament ' cyclothyme ' or ' extraverted ', the latter has ' esthenic ' build associated with a ' schizoid ' ' introverted ' temperament. *(See also* aracterology, J8.)

e Interplay of Heredity and Environment.

But all this has to be modified because the intrort and extravert are obviously at the extreme ds of a normal curve of distribution so most ople fall in between the two and both attitudes n be considerably modified by cultural factors. n extravert, who would naturally be given to lkativeness and the strong expression of his notions, if born into a Red Indian tribe, where e approved basic personality structure is the passive and silent man, would become just as passive as the rest. Even intelligence, the only ental trait which we know *for certain* to be inrited, can be considerably modified by environental factors which encourage or discourage its ll development. Furthermore, there are two her considerations to be taken into account: st, not every trait that a child is born with is herited, and second, heredity may have an direct as well as a direct effect on character. That a child is born with is congenital, but conenital traits are not always inherited or drmined at the moment of conception; for we now that what takes place whilst the child is deloping within the womb also has a potent inence on its future life, usually for the worse. hus German measles in the mother, birth injury, d drugs such as thalidomide taken in the early eeks of pregnancy (*see* P4) can cause severe ental defect or physical deformity. Again, the ffect of inherited characteristics may be indirect epending upon how they are regarded by the ociety into which the child is born and the way e child reacts to the views of his society. For xample, a mentally-retarded or brain-damaged erson may be regarded with contempt or pity in he group or be thrust into a position of high atus as a witch-doctor or sorcerer in another. boy who is short in stature may become neurotic nd a failure when he is teased by his associates r, on the other hand, may compensate by beoming powerful and dominating to cover up his eficiency. The influence of heredity is therefore ery complex and even the most fixed traits may e considerably modified by environment; stature inherited, but without adequate diet the full ature will not be reached, whereas given better ourishment it will. The youth of Britain today re on the average considerably taller than their randparents, and the Japanese who were always egarded as ' naturally ' small are becoming taller s the economic position of their country improves. leredity, by and large, does not determine the etails—it merely sets the limits.

hild-rearing Patterns.

It follows that, though we are prone to think of he child as a pre-fabricated structure waiting at irth to be erected, for better or worse, by the dults who look after it, this is a wholly mistaken elief, because *prior to an infant's earliest contacts ith other human beings it simply does not exist as a 'person' at all.* All we have is a living thing ith certain physical characteristics, a *potential* ntellectual level which, again, without the intervention of people could not raise him above the evel of an idiot or a chimpanzee, and a bundle of iological drives such as hunger, thirst, sex, and he needs for sleep and warmth which only others an satisfy. Human beings are unlike animals in their prolonged period of helplessness, in their ability to communicate by speech, in the possession of an opposable thumb which makes it possible to carry out delicate manipulations, in the fact that they alone can hand on knowledge or culture from one generation to the next and, above all, in having no instincts. Correctly used, the word ' instinct ' refers to behaviour inherited in the structure of the nervous system, unlearned, and relatively unmodifiable; it is typical of the lower animals which automatically carry out quite complicated actions such as nest-building, yearly migrations, courting behaviour, and so on, without having been taught how to do so. In the higher animals such as apes this is already a disappearing category and, so far as human beings are concerned, it has disappeared altogether, being replaced by undifferentiated drives or needs that are inherited, but require the help of a family before they develop into the patterns for satisfying them approved in a given society.

The Sense of Self.

The need for food like the need for sleep, is innate but from a very early age the child learns not merely to demand food or sleep as such, but certain kinds of food and certain hours of sleep which it has been taught are ' right ' and ' good '. The basic psychological process occurs in a particular direction: the infant has physical needs which demand satisfaction, it becomes aware of the world around it, interprets it, responds to it, finally responds to the results of its own response. It feels sensations of hunger, becomes aware of the breast, interprets it as a source of food, sucks it, and depending upon whether its experience is satisfying or not, feels pleasure, anger, or anxiety. Because the way in which people or things respond to our approaches to them influences our attitude towards ourselves, it has been said that the self is based on " the reflected appraisal of other people ", or more dramatically by an Italian novelist, that " the self is the meeting-place of all relationships ". In other words, we do not just *have* experiences, we *are* our experiences and in later life we treat others as we interpret the way they treated us during the formative years, and value or dislike ourselves as we believe we were valued or otherwise. This too is important in understanding certain types of delinquency, because one can only give as much love as one has received, and a delinquent who has suffered from parental neglect may become what is known as a ' loveless character ' because he literally has no love to give and can only respond with hate. The selfish person does not care for others, but he does not care for himself either.

2. THE FORMATIVE YEARS.

The Fundamental Need for Love and Protection.

The biological needs of hunger, thirst, and the rest, by reason of the utter helplessness of the human infant, cannot be satisfied unaided, so there arises very early in life the most fundamental of psychological needs—the need to be loved, protected, and cared for. Love is not something we are born with; it develops through a series of stages from mere cupboard love to a mature and disinterested affection for other people. Hate is an emotion which arises when certain needs are frustrated—in fact, it might almost be said to be a derivative of love since, together with anxiety, it is initially aroused by fear of loss of love. This need to be cared for leads in later life to the need for personal affection and subsequently to a desire for the approval of society so, as one psychologist puts it, love forms " the underpinning on which all the later motives and the cultural imperatives are constructed ".

The Formation of Basic Attitudes.

During the first five years of life the child begins to learn, not only by the process of conditioning whereby it comes to associate two quite different stimuli together as a dog learns to associate the the sound of a whistle with food because one has always followed the other, whilst ignoring the sound of a bell which has been unrelated to food,

but also by a process of trial and error and by imitating its parents. Habits are established by differential reward and punishment, indulgence and deprivation, or the implied threat of deprivation of affection on the part of the parents who make use of the infant's needs to avoid harm and obtain approval and the satisfaction of its biological drives to this end. The habits acquired at this stage relate to sleeping and feeding, bowel and bladder control and the child's early loves and hates (Œdipus complex) within the family circle. Throughout this period it develops attitudes towards its father and mother, brothers and sisters, which becomes the model of its attitudes towards all the people it meets subsequently. So, whilst the core personality is being laid down, the child is not only learning control of its excretory and feeding functions but also how to deal with people; if it is not given affection freely, consistently, and unconditionally, it will soon discover more devious ways of getting attention. If being sick produces the required results, the child will grow up into the sort of person who tries to get affection by taking refuge in real or imaginary illnesses when trouble threatens. If keeping to oneself works (" If I leave people alone they won't harm me "), he will be unsociable, and if a domineering or aggressive attitude works that is what he will become. Naughty and ultimately delinquent behaviour sometimes arises from the child's feeling that he is not cared for (" All right, if you don't love me, at least I'll see to it that you have to give me *some* sort of attention ")

The important point is that all our most basic attitudes arise because at one time they demonstrably worked. As a child psychiatrist expresses it: " We become acceptable or non-acceptable, helpless or capable, important or insignificant, passive or aggressive, busy or lazy, resourceful, or cautious, or sweet, or clever, or polite, or thoughtful, or obedient, or demanding, or a thousand and one other characteristics. These are the traits which are produced by the child and structuralised into his very self because of their *functional* value to him in the earliest years of life. Each one was the trait that worked best and got the best results in the particular setting in which he was placed."

How the Personality Develops.

Parents usually think of child-rearing as a simple—or at least theoretically simple—and direct process whereby 'good' behaviour is inculcated and 'bad' behaviour discouraged by reward and punishment, personal example, and later by speech. Unfortunately this is not the case because, though these are important, other facts must be taken into consideration. To begin with, character formation starts from the very earliest weeks and those traits which are learned then are the most potent by reason of the Law of Primacy which states that the earlier an experience the greater its effect. This is because from birth onwards the way we interpret a new experience depends on our previous mental state: for example, though a child will certainly have no conscious memory of satisfying or unsatisfying emotions at the breast, these are nevertheless built into its brain structure and cause it to see later events in a hopeful or depressing light.

Early Infancy.

There is very good evidence that in the first six months of infancy we have already acquired basic traits which make for an authoritarian or humanitarian outlook and, in fact, the words of the song by Gilbert and Sullivan to the effect that " every boy and every girl that's born into this world alive is either a little Liberal or else a little Conservative " are quite literally true with the single modification that we are not born that way but learn these attitudes at the breast. Of course, like the introvert–extravert scale and the level of intelligence, these attitudes are distributed over a normal curve so that most people fall somewhere about the middle, and the radical-conservative scale is not meant to refer to any political party, though it will clearly influence later political beliefs.

Again, it is almost certain that such traits fussiness, punctuality, belief in discipline, excessive concern with cleanliness, and extr (but repressed) aggressiveness are learned, by direct example, but are intercorrela attitudes associated with an over-strict emph on bowel training. Those nations which v punctiliousness, obedience, and strict hyg (*e.g.*, the Teutonic nations) are also likely t aggressive, obsessed with bowel functions (Martin Luther), and to make jokes, not as other countries about sex, but about lavatorie

The Beginnings of Conscience.

At a later stage, about the age of five or six, child normally passes through what is known the Œdipus complex when it loves the parent the opposite sex and feels correspondingly jeal of the parent of the same sex as a rival and t influences its attitudes towards the opposite throughout life. But quite soon it begins to alise the futility of this state of affairs and f then on two important things happen. Fi the child leaves behind the stage when its mo controls came from outside, from the orders of parents, and by a process known as ' introjecti takes the parent's moral attitudes inside its This is the earliest beginnings of the adult c science which initially starts as an ' internali parent ' exercising control from within instead having it superimposed from without. Seco the child now begins to imitate the parent of *same* sex, and in this way the boy learns how play the masculine role as defined in his soci the girl to play the feminine role. This is a v important stage and in households where father is absent, badly behaved, or a weakli the boy may imitate his mother and deve homosexual tendencies in later life.

Child–Parent Relationship.

There are therefore two parallel processes volved in child-rearing, the one conscious deliberate in which the child is taught to beh according to the rules of its society and also lea in the academic sense, but the more signific one is an unconscious process because, as we h seen, many of our most deep-rooted traits a during the period when the child cannot und stand speech and are the result of an interact between parent and child at a time when parent is unlikely to realise the values he or sh actually inculcating. In short, the child is ponding more to what his parents *are* than to w they *say*, and therefore *the basic rule in bring up a child is to give it unconditional, secure, consistent affection.* But it is only the norm parent who is able to do this and, since not ma of us have reached full emotional maturity, children may appear to be getting plenty affection, but the true reasons for the mothe behaviour may be guilt at not feeling enough l or, if she is unhappy with her husband, she m be displacing her frustrated affections on her so in neither case is the love healthy or genuine a the child will suffer.

Even the formal educational process is influ ced by these emotional undercurrents which parents neither understand nor are capable controlling, and the child will accept or rej what it is deliberately taught, not in terms of truth or real value, but rather in terms of unconscious (or sometimes conscious) feelin towards the parent who tries to inculcate the The boy who either unconsciously resents father or is striving to become independent unduly possessive parents (or even, as sometim happens, trying to avoid being overwhelmed the reputation of a well-loved but very famo father) is more likely to reject his father's religio philosophical, or political views than to acc them. One little boy whose very tolerant pare had never uttered a word of condemnati against his lack of interest in books were distress to hear him say when he thought they were listening, " Of course, I'm the idiot of the family —they had *said* nothing, but the walls of th home covered with bookshelves filled with boo many of which they themselves had written, h said a great deal. The boy excelled at getting with his schoolmates and at sport, but until t

asons for his attitude against learning were inted out to him, he did not do well academi- lly. Once he had learned what was going on his unconscious, he became one of the best nolars in his college.

3. THE UNCONSCIOUS PROCESSES SHAPING PERSONALITY

ie Repression of Emotions.

In general, we only pay attention to those ements of our environment which (*a*) fit in with e rest of our beliefs, and (*b*) help to further the tion in hand at the moment. Freud, the foun- r of psychoanalysis, pointed out that all those notions and thoughts which are repugnant to e individual are either pushed into his uncon- ious or never allowed to leave it. They are, as eud said, "repressed"—a term which does t mean the conscious *suppression* of anti- cial desires, but the refusal even to recognise eir existence. (*See also* **Freudian Theory, ction F, Part III.**) However, as others have inted out since, it is not only those aspects of rsonality which are regarded as morally objec- nable that come to be repressed, but traits hich, whilst not necessarily ' bad ' in themselves, not fit in with conscious attitudes. Charles arwin, for example, admitted that, as he became ore and more absorbed in reasoning and scientific esults, he lost the ability to enjoy, as he once d done, the pleasures of poetry and literature. e shall see later that one of the great barriers to anging attitudes from whatever motive is the ct that, after they have grown up, people do not nd to seek new experiences but rather to rein- rce existing prejudices.

For the moment, however, we are concerned th those emotions and desires which are re- essed in the original Freudian sense. When ch emotions are repressed they do not cease to ist and sometimes have quite devastating effects the individual and his associates. Thus those ho have been brought up to repress their ei- r aggressiveness may repress it and, by the ocess known as 'reaction-formation', become mpulsively 'gentle'. Their assumed 'gentle- ss' is adopted in order to fight their 'bad' gressive side; and so we often find (and this is e tragedy of these movements) that those who e pacifists, vegetarians, and against cruelty to imals or children cannot help their latent gressiveness from leaking out. This leads to ch unpleasant phenomena as the obvious ten- ncy to fragmentation and quarrelsomeness ithin pacifist movements, an unhealthy absorp- on in cruelty quite frequently in situations where hers see none, and extreme intolerance. Jung scribed this unrecognised aspect of a man's ture as his "shadow", giving as an example a an he had once met, a Quaker, who could not agine that he had ever done anything wrong in s life. "And do you know what happened to s children?" Jung asked. "The son became a lief, and the daughter a prostitute. Because the ther would not take on his shadow, his share in e imperfection of human nature, his children ere compelled to live out the dark side which he d ignored." Thus unconscious attitudes in the arents are sometimes more potent in influencing eir children than the respectable conscious ones.

ental Mechanisms to Guard Our Self-Esteem.

Since everyone has had to repress quite a lot of nacceptable material (and, of course, the indivi- al has been *taught* to reject it though it may be armless enough in itself and infinitely more angerous repressed than openly recognised), the ind has learned many tricks for concealing those aits or memories from awareness. These forms f self-deception are what Freud described as mental mechanisms" which permit some form f expression without allowing knowledge of its ource. These are explained under **Freudian heory, Section F, Part III.** The lesson to be arned is that the proper way of dealing with pressed emotions is (*a*) to recognise them, and) to sublimate them—i.e., *consciously* direct hem towards socially useful ends. Many who ave helped the poor and sick have been stimula ed to do so because of their own unhappy child- hood experiences and those who have done some- thing useful on behalf of small underprivileged nations or classes have usually been well aware that it was their own early experience of being underprivileged that caused them to do so.

The Nature of Aggression.

Hardly any subject in the whole field of psycho- logy is more important than the problem of aggression, and it is doubtful if any is less under- stood by the layman. This is little short of tragic since it is obvious that what is generally comprehended under the name of aggression is responsible for many of the issues facing us today: for example, warfare between nations, crimes of violence, race prejudice, and the concern felt by many about violence on television or in children's 'comics', all reflect the necessity for taking the matter seriously. What stands in the way of genuine understanding is the fact that, as is so often the case in psychology, most people are not only convinced that they already know all that needs to be known but, worse still, they are confi- dent that they know the solutions. What could be more apparent than that war is caused by the 'instinct' of aggression, that violent crimes can be cured by violence, or that horror scenes in comics or on television are a cause of juvenile delinquency which can therefore be reduced by preventing children from being exposed to them? Naturally enough, anyone who is rash enough to attempt to show that these are dangerous de- lusions or that, to say the least, the problem is much more complex than is often supposed, is immediately suspect of blinding himself to realities or of being 'soft' when the correct attitude is to be 'hard' and 'objective'. However, the reader is invited to try to see the other side of the picture.

Life Energy or Drive.

In the first place, 'aggression' is not a simple entity synonymous with 'hate', and this con- fusion leads to the belief that what is a perfectly natural and inborn tendency is, without qualifi- cation, evil. Actually, as Dr. D. W. Winnicott, who is one of the most eminent British psychoana- lysts (*i.e.*, those who treat patients by the methods based on the theories of Freud) has pointed out, "at origin aggressiveness is almost synonymous with activity". It is not an 'instinct' nor even a specific drive but the natural tendency to over- come obstacles to the attainment of goals without which life itself could not exist: thus we talk about 'attacking' a problem, 'struggling with' and 'overcoming' a difficulty, 'mastering' a subject or 'getting one's teeth into it'.

Hate or Anger.

In this sense aggressiveness is simply life-energy which, when it meets a barrier to satisfaction (whether the need for satisfaction involves solving a mental problem or looking for one's next meal) accumulates in order to summon up enough power to overcome it. This sort of behaviour is happen- ing to everybody at every hour of the day and usually the barrier is successfully overcome and the organism returns briefly to the original resting state. But if it proves insurmountable, a state of frustration develops which leads to emotions which can be described as 'aggression' in the more limited sense of the word implying anger, anxiety, and hate. Hate arises in interpersonal situations, that is to say, it is something we feel towards *people*, arising originally from fear of loss of love which threatened our security in infancy because an unloving mother could not be relied upon to satisfy our physical needs, and subsequently it arises in situations where security is threatened either in the emotional sense or when there exists a real or imagined physical danger to status, life, or property. For example, rejection in love threatens our self-image by damaging that per- sonal esteem which is the badge of psychological security, and the fear of attack from other individu- als, groups, or nations threatens our physical security, so both are prone to lead to hate. *Since hatred is so closely linked with anxiety, anxious and insecure people are particularly prone to irrational hatred.* Thus revolutions are not made by the secure ruling classes who have nothing

to gain, nor (as the Communists have learned to their cost) by the very poor who have nothing to lose, but by the insecure lower middle classes; those who incite race riots in the southern states of America are not the well-to-do or the old 'aristocracy' who are often, in private, quite liberal in their views, but the 'poor whites' whose only claim to superiority rests on their colour. Anger, though often directed against people, is also aroused by situations or things which frustrate the individual, such as the car that fails to start; hate always involves people, anger does not.

How Aggression is Dealt With.

When a great deal of anger or hatred (i.e., aggression in the narrower sense of the word) has been aroused, various possibilities of handling it arise. The normal reaction is to assess the situation rationally and consciously recognise one's feelings for what they are; from this point one may feel that by an increased effort the barrier to satisfaction may be overcome and decide to carry on, or that the barrier is genuinely insuperable so that further effort would be wasted and that, failure being no disgrace in the circumstances, one can without loss of self-respect redirect one's efforts elsewhere. Unfortunately, in our own culture children are often brought up to believe that anger, aggression, or even normal self-assertion are 'bad' emotions to be suppressed just as much as 'evil' sexual desires. When this happens, what was once consciously suppressed by the threat of punishment or loss of love in childhood soon comes to be automatically and unconsciously repressed in later life. In this case our aggressive feelings (which, as mentioned above, may sometimes extend to what is merely self-assertiveness or the right to develop oneself as an independent individual) are dealt with by *denial*—we deny that they exist at all, or assert that they exist in other people but not in ourselves, or direct them against a socially-accepted scapegoat. That is to say, they are repressed, projected, or displaced, and this is the cause of most of the troubles facing the modern world. Those who lead campaigns for peace, if in many cases genuinely gentle people or motivated by a commonsense realisation that the human race must choose between international peace or total destruction, are all too frequently individuals who are compulsively 'gentle' in a neurotic attempt to deny their own destructive tendencies. But the denial of such tendencies does not prevent their manifesting themselves in such a way as to frustrate the achievement of the avowed goals of the movement and, to quote Dr. Winnicott once more: "*If society is in danger, it is not because of man's aggressiveness, but because of the repression of personal aggressiveness in individuals.*"

The Effects of Repressing Aggressive Feelings.

Normal sexual or aggressive feelings when denied give rise to those horrible sexual and aggressive fantasies which, when projected upon the outer world, lead to that race hatred when the victim of what is in fact a diseased imagination pictures his womenfolk being raped by Negroes or himself being dominated by designing Jews. The problem of war will be discussed elsewhere, but it is worth while noting here that one of the main reasons why warfare occurs is that for masses of frustrated people it is the most obvious way out of their frustrations; in fact, if we do not exactly *want* wars there are millions who *need* them. Freud pointed out the apparent paradox that a nation is never so much at peace within itself as when it is fighting an external enemy, from which it follows that countries which have long been living peacefully with their neighbours will have more aggression to direct inwardly. That this contains more than a grain of truth is evinced by the high suicide rate in such countries as Sweden and Switzerland, and Jung, himself a Swiss, referring to the peculiar bitterness of Swiss internal politics, made the remark that his people had "introverted war".

But there are some people in whom any self-assertive or aggressive manifestations have been so thoroughly repressed that they are permitted hardly any expression even in the forms described above; such individuals are as embarrassed a anxious at the least sign of anger or self-assert in quite normal circumstances as the prude upset by things with a sexual connotation wh the ordinary person simply does not not When this occurs the only possible solution is *introject* the aggression (i.e., turn it against self), and this leads to severe states of depressio which is really self-hatred—to actual suicide, to psychosomatic disorders such as high blo pressure brought about by prolonged str Finally, it must be remembered that suicide is the only form of self-destruction, that chro alcoholism, drug addiction, accident-pronen and other conditions are often unconsci attempts to walk slowly or rapidly along the r to death and failure, resulting from inward directed aggression. These are, of course, sta that *may* be brought about by introjection, thou since different people have different levels tolerance and stamina they do not invaria occur; what we can safely say is that, as agg sion in its original aspect is a manifestation of drive towards self-assertion and self-realisation, repression will *inevitably* lead to impoverishm and inadequacy of the personality.

4. THE FIVE AGES OF MAN.

Disregarding Shakespeare's account of seven ages of man, we shall describe for the s of convenience a mere five: childhood, ado cence, the period during which we can still ho fully expect to be described as a young bache or married couple, middle age, and old age. E of these age groups has its own special proble so it is necessary to observe the process of devel ment and the satisfactions and difficulties aris at each stage whilst remembering that many not most, of these difficulties arise in a so context and cannot be usefully considered terms of the non-existent isolated individu For example, though we in the West commo (and not without justice) regard adolescence a period of 'storm and stress', this is not the c in other societies, and therefore must be regar as a socially-conditioned phenomenon. But si most people tend to regard their particu problems as unique and 'inside' themselves, so of these will be mentioned here, whilst in Part other problems will be discussed and it become evident that, in fact, *all personal probl are also social problems.*

The childhood years are the formative years s what we later become can only be discussed their light; furthermore, the child only experi ces society indirectly through the medium of family and, initially at least, is the only t individualist until moulded into the image society. What we have so far been discussing the basic principles of dynamic psychology wi out which none of the rest of this section could understood. Whilst the problems of the ch are to some extent peculiar to the particu family even when it acts under social pressu those of the other age groups result from inter tion at first hand with society. The difficul of the other age groups are not *related* to socie but in large measure *created* by society. whilst adolescence, young married life or bachel hood, and old age have their problems, th cannot usefully be discussed outside their so context and properly belong to Part II. H true this is will be shown in what follows.

THE CHILD.

A child is described as an *infant* from one mo until he is able to walk at fifteen or sixteen mont a *toddler* from fifteen months to the age of 2 *preschool* child from 2½ years to 5 or 6 years, an *child in middle years* from 6 to about 12 ye About the latter period he has, with fairly w variation, reached *physical* maturity, but it not until the end of adolescence that he reached *social* maturity. He can follow a mov object with his eyes at about 4 weeks, con his head about 16, grasp and manipulate obj at about 28, crawl and sit about 40, and stand move around at 52 weeks or slightly later. it is important for parents to recognise that though all children grow up in the same way, t

o so at different rates. You cannot *teach* a child walk; it will do so when it is ready, *i.e.*, when has reached that stage of controlled movement.

arental Behaviour and its Effects on the Personality of the Child.

Something has already been said about the way which the personality develops and there is od evidence that important traits have arisen ng before the child is able to speak or understand eech; whether he tends to be tolerant of himself nd others is probably determined in the first six onths of life. Then, and even after acquiring eech, he responds more to what the parent is an to what she (because at that time it is the other who is the important person) deliberately ies to inculcate. For example, a nervous and nse mother or one who secretly dislikes the rocess of breast-feeding cannot help but convey ese impressions to the child through body nsions and the adequacy or otherwise of the flow milk. The two problems facing the infant at he breast are, first, that it is unable to foresee the ture and so it takes some time before it comes to arn that its hunger and thirst will sooner or later e suitably appeased; second, that its emotions re of the all-or-none type which it is not yet able deal with and therefore even momentary frustation of its needs brings about outbursts of ncontrollable rage. In short, it alternates etween states of satisfaction and fury, and the tter are so frightening that it may *introject* them n which case it feels that there is something bad ' inside itself) or *project* them against the ustrating breast or mother (in which case it will el that mother is ' bad ').

he Mature Personality.

All of us employ both of these mechanisms to eal with infantile aggression and what we later ecome is influenced by which one predominated; here is at one extreme the type of person who, hen things go wrong, tends to feel ' I am bad ' nd at the other the type who will tend to blame thers. The former will develop the sort of onscience based upon fear of having disappointed r hurt something that is loved (*i.e.*, will have umanistic attitudes), the latter will have the sort f conscience based upon fear of punishment (*i.e.*, e will have authoritarian attitudes). As we hall see in more detail later, both of these extremes re undesirable; for it cannot be too often emhasised that the fully mature personality is one hose relationships are neither self-denying nor enying the rights of others but one *based on utual acceptance and respect*. The man or woman ho denies his or her own rights as an individual nd becomes dedicated to ' helping ' others herely in order to assuage personal guilt-feelings just as abnormal as the one who projects his ' bad ' emotions into the outer world; neither is notivated by anything better than a neurotic ttempt to solve personal tensions. Genuinely elpful people are motivated by that overflow of ve for humanity which can only arise from love nd respect for themselves and that, as we have een, comes from the experience of deep and satisying parental affection in childhood.

he Neurotic Personality.

The effects upon the personality of over-strict owel control have already been mentioned and his sort of parental behaviour leads to the bsessional type of basic personality structure hown in some of the peoples of northern Europe here the approved attitudes are seriousness, hard ork, punctuality, acquisitiveness, authoritarian ubmissiveness (*i.e.*, a heirarchy in which one does ot mind being kicked so long as there is an inerior who can be kicked in return), and repressed ggression manifesting itself in a superficial entimentality or the search for a scapegoat. Heinrich Himmler, whilst responsible for the murder of six million Jews, was also a leader in he society for prevention of cruelty to animals in Germany. In southern Europe, on the other hand, where parents are more lenient in this respect, the general attitude is easy-going, impulsive, warm, and not over-concerned about the passage of time. It is true that many Latin are indifferent to animals, but they have no need (as in some other countries) for a society for the prevention of cruelty to children. It should hardly be necessary to repeat that nobody asserts (*a*) that all people who are kind to animals are necessarily motivated by a ' gentleness ' which is merely a cover-up for concealed sadism, since many of them are just naturally gentle people to man and beast alike; nor (*b*) is it asserted that there is necessarily an inverse relationship between the degree of affection shown to animals and that shown to people. Obviously the ideal is to be kind to both. But nobody who uses his eyes can fail to see that some people love animals to the exclusion of human beings and that many gentlewomen who are good to their cats are very vocal in informing us that they would " beat a man to death " for whipping a horse, and regular in their attendance at conferences where motions are proposed for bringing back the birch and reimposing capital punishment. Of course, they are perfectly entitled to these views; but they are certainly not entitled to regard themselves as kind and loving or opposed to aggression. Such people are merely displacing the affection normally felt for their fellow men on to animals as the substitute object, or displacing their aggression from its true cause in their personal frustrations towards other substitute objects which happen to be the socially accepted scapegoats of society.

Sexual Development.

Just as ' aggression ' has a general application signifying life-energy or drive and the narrower and more common application meaning hatred or anger, so the word ' sex ' has a general and a particular meaning. The former is more or less synonymous with ' desire ' and this type of sexuality is present from birth, manifesting itself first in the pleasure of sucking where the source of pleasure is the mouth, later in the interest in bowel motions which children experience during the ' house-training ' period, and subsequently in the more overtly sexual feelings of the young boy towards his mother and the young girl towards her father at the Œdipus stage. At this stage, about the age of five or six years, the child becomes interested in its sexual organs—though even quite young babies often show a similar interest. All these stages of immature sexuality are described as ' autoerotic ' because the main object of love is the self and other people are seen in terms of the degree to which they satisfy or frustrate the child's self-love. Masturbation is natural at this time and later attitudes to sex will be strongly influenced by parental attitudes of permissiveness or severe prohibition since the latter may cause the individual throughout life to feel that sex is something ' dirty ' and ' sinful '—a belief which has ruined many a married life. The question of masturbation in later life will be dealt with when adolescence is discussed.

With the passing of the Œdipus stage, the adult conscience begins to develop on the foundations already laid in the early months of life and the parents' values are internalised as the ' still small voice '. However, it must not be thought that this is the whole of conscience because it is still primitive and in later life continues to develop with the formation of an ' ego-ideal ' when we consciously try to imitate the behaviour of those we admire and respect. With puberty the sexual drive becomes directed towards the other sex and the child is physically mature, but this level is preceded by a homosexual phase in which the object of love belongs to the same sex. This does not mean that overt homosexual behaviour necessarily occurs, though it is not infrequent, and according to the Kinsey report, the majority of American males reported such experiences, but in this country its most obvious manifestation is the ' crushes ' felt by schoolgirls towards attractive teachers or senior girls and the similar behaviour among boys when they admire other schoolboy friends and think girls silly. However, what actually happens depends upon social factors; homosexuality is common in public schools whether overtly or in a more sublimated form, and much less frequent among those who have been lucky enough to be reared in a more natural environment where extreme segregation of the sexes does not occur.

Thus the course of sexual development is a gradually moving away from self-love (autoerotic), by way of love of someone of the same sex (homosexual), towards the wholly other (heterosexual). But since nobody completely leaves behind all the manifestations of the various stages through which he has passed, everyone has homosexual and autoerotic elements in his or her personality.

The Subjective Life of the Child: Fantasies.

No child can avoid the various conflicting situations which are part of the process of growing up from infancy to puberty and after; for, to take the more superficial difficulties first, every child must feel small and helpless in the great world of adults, feel jealous of older brothers or sisters, and even more so of the new baby who intrudes upon his supremacy in his parents' attention, just as the new baby will later feel a particular need to clamour for attention in face of the existing competition.

Now these are some of the situations that are dramatised in fairy-tales and the ancient myths (which have been described as the "dreams of a people"), and form part of much great literature and art. Whilst an obvious function of art is its aesthetic aspect when the artist creates something of beauty, it has another function which Aristotle describes as 'catharsis' (*see also* I6)—that is, by moving people to pity, love, or terror, it helps them to discharge emotional tensions and even to resolve their conflicts by enabling them to see that their individual problem is part of the whole human situation, and by pointing out reassuring solutions. Thus art is a form of psychotherapy and, of course, is often deliberately used to that end in the treatment of mental illness. Keeping at the superficial level, it is easy to see that two very pervasive and readily interpreted themes in fairy-tales are the giant-killer theme which reassures the child that the frequently awe-inspiring 'giants' of the adult world are capable of being dealt with and have their weaknesses, and the theme which pictures the youngest son as the 'hero' who accomplishes all the tasks the older brothers have failed in and wins the hand of the fairy princess. But at a much deeper level there lies a darker and more sinister set of fantasies shared by all of us in a world peopled by demons, witches with iron teeth who devour children, the wicked stepmother who wishes to poison her lovely stepdaughter, all of which are depicted in such tales as 'Hansel and Gretel', 'Snow-white', 'Rumplestiltskin', and the rest. The great Greek plays centre around such incredible plots as that of King (Edipus who kills his father and marries his mother, or Princess Electra who connives at the death of her mother who had murdered her father Agamemnon (*see* H24), and the myths of all countries tell of infants born out of the mouth or navel, of castration, incest, and milder stories such as that of the unknown child reared by simple folk who turns out to be of royal blood.

These horror-comic themes, in short, are universal not because some eccentric invented them but *because we have all experienced them in real life.* The child unsatisfied at the breast has fantasies of devouring the breast and, when these are projected, they reappear as the mother who wishes to devour the child; the mother in one stage of infancy is divided into the good satisfying mother and the bad devouring one, the former becoming the 'fairy godmother' and the latter the witch or evil 'stepmother'. Shakespeare's *Hamlet*, incidentally, is a good example of this mechanism because Hamlet was actually jealous of his late father's possession of his mother but, being unable to accept that the father he also loved could be hated, the wicked uncle-stepfather is made to bear the hated side; psychologically speaking, the bad stepfather and the good murdered father are different aspects of the same person and Hamlet has projected his own incestuous desires for his mother upon the stepfather. Many children quite consciously have the feeling that their mother is not their true parent and that they have more exalted origins. This necessity to think in terms of a good parent and a bad one is later replaced by the realisation that there is simply one individual who is sometimes lovable and sometimes hateful and this ambivalence, *i.e.*, having mixed feelings for the same person, is a step towards maturi though later it will be replaced by a more d criminating picture of goodness and badness bas not on how people react to us in satisfying unsatisfying terms, but on more objective st dards.

There are two main conclusions to be dra from this analysis of the fantasies of the child:

(1) that children are far from 'innocen in the Victorian sense and have experienc far greater horrors in their own minds than c be introduced from outside. They enjoy, example, Grimm's fairy-tales because *in atmosphere of security* at the mother's knee by the nursery fireside, their conflicts objectified and the story has a satisfy ending which helps to resolve them.

(2) that the normal child is the ambivale child who has received enough sense security from its parents to be able to expr openly its alternate affection and resentme which, beginning at an early age, becom increasingly evident as it grows older whe conflict arises between the need for dep dency and its ever-increasing need independence and self-realisation. Lar scale studies have shown beyond shadow doubt that, ambivalence is characteristic the normal child; obedience, dependen and unnatural 'goodness' or compliance characteristic of the neurotic child; a complete lack of feeling is typical of t potential delinquent.

Intelligence Tests.

All that will be considered at this point is t general validity of intelligence tests and the f tors which may influence their results.

Intelligence is simply defined as that whi intelligence tests test and, by and large, such tes are correlated with school success—though would be more accurate to say that these corre tions are sufficiently high to be useful but not high as to exclude other factors in which t personality is involved as predictors to succe As one authority puts it, what is tested are th qualities that happen to be useful or regarded valuable in the industrial society in which we li Recent work seems to suggest that most of th who do well at school are almost certain to do w (other things being equal) in fairly pedestrian a conventional jobs in which hard work, knowled intelligence, and not too much imagination s required, whereas genuinely brilliant children wi novel ideas may do rather badly simply becau though equally intelligent, they are original a rebel against discipline. Intelligence is defin (*a*) in terms of mental age or M.A., and (*b*) in ter of the intelligence quotient or I.Q. (These ter are explained in Section L under Intelligence.)

Measurement of Mental Ability.

Since intelligence, like other dimensions personality, is distributed in a bell-shaped cur with the average people at the top and the ve intelligent or very dull at either end, we can s that the *normal* category (including 50 per cent the population) has I.Q.s from 90–110. Th with an I.Q. of more than 110 are in the upp fourth of the population. I.Q.s from 110–1 place the individual in a *superior* category, 12 130 in the very superior category, and from 13 140 in that of the *near-geniuses*. Geniuses (in t technical, not the popular, sense of the word) a those with I.Q.s of over 140 and include less th 1 per cent of the population. At the other end the scale are the *dull normals* (80–90), the *borde line mentally deficient* (70–80) and the *menta deficient* (70 and below). The latter group i cludes the dull and backward or *morons* (50–7 *imbeciles* (20–40), and the *idiots* who fall below 2

Mental ability, as measured by intelligence tes reaches its peak between the ages of 14 and 20 a subsequently declines slowly until old age, thou no great decline appears before 50 and even th it is not marked. However, this slow decline intelligence is compensated for by greater abili due to increasing knowledge and experience, whilst John Stuart Mill was obviously a genius

age of three and most scientists who achieve rthing do so by the age of thirty. Verdi's atest operas were composed when he was over hty. Nor is there any necessary correlation ween greatness and high intelligence; for ugh such men as Mill, Coleridge, Macaulay, pe, and Voltaire, according to retrospective imates, would have had I.Q.s in the region of 170–180 group, those with I.Q.s of 100–110 uld have included John Bunyan, Cervantes, ther, Rembrandt, William Cobbett, and the et Dryden. Gifted people include not only the ademically and technically gifted, but the ative and socially gifted.

luential Factors.

Among the factors known to influence the result intelligence tests are learning how to do such ts (in other words, this is an ability which to ne extent can be acquired); better education, cause it has often been demonstrated that even entical twins with the same heredity and there- e the same basic intelligence can have different e.s, the twin with the better education some- es having an I.Q. of ten or more points above e other; city children do better than country ldren with an average I.Q. difference of 6½ ints because the city child is exposed to more mulation; foster-children sent to poor homes y show a *loss* of their initial I.Q. of up to 47 ints, whilst foster-children placed in good homes y gain 20 or more. Although gifted children ne from all social backgrounds, a middle-class tural background is a great advantage as it ovides the intellectual stimulation the child eds to develop its gifts. Psychological factors also important and those with so-called obses- nal traits of carefulness who are always looking ck to see if their previous answers were correct penalised in comparison with the confident ld who works fast. As regards sexual differ- ces, and those connected with race, we know ere are no significant differences between the ces in overall intelligence and that men do better some tests, women on others. One of the ghest I.Q. scores ever recorded was that of a gro girl in North America.

We must remember that although the nature of n's mental reactions may be determined at the oment of conception, it is his external environ- nt, particularly in infancy and childhood, ich determines his subsequent development, ntal as well as physical. In many of the areas the world where people are suffering from mal- trition, protein deficiency in the very young efore and after birth) may have lasting effects intelligence. As their mothers are also under- urished, such children start life with a per- anent handicap.

Elsewhere we have noted the importance of the ild's attitude towards education in relation to rental attitudes towards the child, and when we me to discuss industry it will become apparent at many countries remain backward in spite of chnical and other aid because of their emotional d social attitudes to such matters as ambition, orking to the clock, financial incentives, and cial change. Those who have always thought society as essentially static and of life as being termined by fate, require to change these titudes before they can bring about their in- strial revolution. It is not lack of intelligence, t socially-conditioned indifference that causes eir problems. Other psychological tests which easure special aptitudes or the personality will dealt with in Part III.

ADOLESCENCE.

Adolescence is manifestly brought about by ysical changes in the body due to changes in the r and other glands such as the pituitary and the renal glands on top of the kidneys. Obvious ddily developments begin to take place: men- ruation, the development of the breasts, and the creasingly rounded contours of the figure in rls, the breaking of the voice, development of e muscles, and the production of semen in boys, gether with the growth of the beard in boys and owth of hair under the armpits and in the genital gion in both sexes. But even these manifestly organic changes are influenced by social factors, both psychological and nutritional, and within the present century the average height of each younger generation has increased and sexual maturity, particularly in girls, begins at an earlier age. Therefore, though these physiological reactions *started* the process, it is very important to avoid ascribing to adolescents in general features which are merely typical of our own and a few other societies. On the other hand, once they have been recognised as non-universal, it is still necessary to consider the characteristics of adolescence in the technologically advanced countries and try to discover their social causes.

The Characteristics of Adolescence in the Technically Advanced Countries.

We can begin by taking two accounts of the traits said to be typical of the adolescent in America, one dating back to G. Stanley Hall in 1908, the other to E. B. Hurlock in 1959. Stanley Hall's list includes (with particular reference to the immediately post-pubertal period): inner absorption and reverie; the birth of imagination, illusions, dreams, etc.; self-criticism, scruples; the over-assertion of individuality; a strong tendency to imitation; the assumption of dramatic poses, roles, affectations; folly, absurdities, freakishness; new speech consciousness; absorption in friendship; intense fluctuations in energy and emotional and intellectual plasticity. Hall likened the manifestations of adolescence to the symptoms of hysteria and insanity, and considered it a period particularly prone to religious conversion and other violent personality changes. Hurlock describes the emotional life of the adolescent as characterised by intensity, lack of control, inconsistency, prevalence of long-drawn-out emotions or moods, and the growth of such sentiments as patriotism, loyalty, and reverence.

Comparison with Other Cultures.

Unfortunately both these catalogues of traits, and particularly that of Hall, show by the very language in which they are expressed the lack of sympathy which, in part, makes the adolescent what he or she is: freakish, given to absurdities, self-conscious about his speech, too individualistic and yet given to self-criticism, lack of control, and the rest. Yet, if some of the features mentioned are dated (*e.g.*, proneness to religious conversion and patriotism are less common than they used to be) and others are obviously more typical of the middle- than the working-class adolescent, as a whole they are recognisably true of our society. That they are far from being true of all, or even many, societies is shown by Margaret Mead's study of Samoa where adolescence brings about no conflict or revolt and no neurotic worries; all children from the earliest age have freely engaged in sexual play and, on the arrival of puberty, the girl engages in a series of affairs with the boys of the community each of which is short-lasting. There are no rules which allow members of certain age-groups definite rights and privileges and in this respect nobody may progress faster than anybody else. So far as sex is concerned, the adults are perfectly well aware of what is going on and make no criticisms nor attempt to interfere in any way.

If one looks behind the lists of traits supposedly typical of the adolescent in our society, it will be found that they can all be compressed into a few fundamental problems or conflicts: there is the quest for identity, the answer to the question, " Who am I? "; the exaggeration of the conflict between dependency and self-sufficiency; and, if frequently the subject of prurient interest on the part of certain adults, the rather less significant sexual problems which do not actually arise at this time, though there is more opportunity to accept or refuse approaches from the other sex, to engage or not to engage in overtly sexual affairs.

No Fixed Rules.

The adolescent in our society is in a confused and precarious position. His childish behaviours are no longer adequate or tolerated and the apparently secure and settled ways of the adult have

not yet been learned—in short, he is playing a game with no fixed rules. Now this is not so elsewhere, nor was it always so here; in mediæval society everyone had a fixed role to play according to age, sex, and social status just as in Samoa, and even just prior to the last war few problems of this sort bothered the middle-class child. A girl was a girl until she left school, possibly at the age of eighteen or more; a boy was a boy until he went to university or started in a job. This, indeed, is still the case in less sophisticated societies where a boy becomes a man at a specific age and the occasion is marked by initiation rites following which he *knows* that he is a man with full adult rights. In many European peasant communities one can tell an individual's position from his (or her) dress: the unmarried girl, the widow, the bachelor, the married couple, all have sartorial indications of their state. Today none of this exists in the technically developed countries: according to traditional morality, sexual intercourse is forbidden before marriage (at least to girls) and yet the period between the attainment of sexual maturity and the possibility of marriage increases for those who wish to advance themselves. There are no fixed rules regarding the age at which certain privileges are automatically obtained; for example, one piece of research showed that in a suburb in a large American city the age at which parents permitted their daughters to go out unaccompanied varied from fourteen to twenty. The law decides when children may buy cigarettes, parents make their own widely differing regulations and it is understandable that those who see this behaviour permitted in others of their own age-group will feel deprived and embarrassed if it is forbidden to themselves.

Moral Standards

The period at which an adolescent ceases to be a child and becomes an adult not only varies widely in general but even varies in relation to specific activities; it is possible to be a 'child' in one field and an 'adult' in others. Hence the adolescent's search for identity, role-playing, imitation of heroes or pop-singers of his own age, self-searching, and resentment of adults. The latter is increased by the ardent moving away from childhood status towards self-realisation as the individual interprets it, and both lead to adolescent assertion, aggressiveness, and the feeling that he is not 'understood'. Nor is he understood, because technical progress and the changes it has brought about in social patterns make even the young parent useless as a model for youth to follow—there is an ever-increasing gap between the generations who cannot understand that each is literally living in a different world and the old rules of even twenty years ago are not always applicable now. Sexual behaviour is as much a sign of revolt and defiance as of genuine sexuality, and having a sexual affair is often regarded as a status-symbol just as smoking in school was a status-symbol before the war. Modern youth is much more knowledgeable about sex than formerly (though still not sufficiently instructed) and therefore less prone to genuinely sexual conflicts than previous generations. Few indeed worry about masturbation, that object of baseless terror to their parents; for they know that it is largely universal and entirely harmless. Of course, many moralists regard it as wicked as they are perfectly entitled to do, but that it is harmless is a medical *fact* which they are not entitled to query. Indeed, the main cause of excessive masturbation is not overdeveloped sexuality but anxiety brought about by threats of this sort.

Good Morals begin with Right Attitudes to Others.

The trouble about sexual morality is that, though some may believe that there are certain fixed standards which determine what is 'right' or 'wrong' in this field—and it is impossible to contradict them because this is not a matter science can usefully discuss—in reality all moral standards have varied widely from one place or time to another. It is clear that the basic revolution brought about by Jesus Christ was a realisation that good morals begin with right *attitudes* to other people and cannot be codified in a fixed set of rules that tell people what they must *not* do, and we have given numerous exam from modern psychology to show that when pe do the 'right' thing for the wrong reason they not likely to be successful in achieving their g Saint Augustine put it even more bluntly whe said: "Love God and do what you like"—o some might say, "If you genuinely care for o people in their own right you can't go far wro

ADULTHOOD AND MATURITY.

Psychological Maturity.

It is evident that society decides when a pe shall be regarded as adult and that, on the wh this bears little relationship to biological matu —much less to psychological maturity whic achieved by few. Among the qualities which the signs of psychological maturity one must t into account:

(1) Emotional control, which implies t the truly adult person has to learn to d immediate gratification of his wishes or pressions of his feelings which must bec subject to his total way of life—he will le that it is not worth while giving way i mentarily to a form of behaviour which only be followed by shame or is likely to all that he has regarded as his highest ide

(2) The appropriateness of his emotion that is to say that, broadly speaking, a mat person's emotional responses are objectiv relevant to the actual situation facing him his expression of feelings shows an awaren of those of others. The problem of achiev emotional maturity is not solved by stamp out or denying emotions, however strong unpleasant they may be; it is a problem learning to live with emotions, keeping th within reasonable bounds, and of turn them, whenever possible, to the ends of s vival of ourselves and others in this com cated world.

(3) The richness and variety of experien whereby the all-or-none emotions of the inf become highly differentiated, varying fr righteous anger or disgust, to wry amusem and the most subtle esthetic pleasures. U fortunately most of us, partly from psych gical distortions arising in childhood partly from lack of stimulation from the vironment such as inadequate educati never wholly reach this stage and it is obvi that some of the greatest geniuses, wh adding to our own capacity for esth pleasures, still remained emotionally child —not with the *child-like* simplicity of a p such as Blake, but often with the vic childishness of the antisemitic Wagner or woman-obsessed yet woman-terrified Stri berg.

Most people are immature in various ways must simply try to make the best of things and probably true to say that many live lives of qu desperation. Marriage takes place for the wr reasons because of modern society's obsession w sex and its failure to see that sex without comra ship, compatibility of temperament, and the preciation and respect due to a partner who human being in his or her own right, is bound fail. Men marry women sometimes as lo status-symbols, sometimes as mother-substitut and sometimes as someone to boss for the lack any other means of expressing their power ob sions—yet, strangely enough, marriage survi and perhaps has never been in a stronger posit as a social institution. But, again, society de mines the form of marriage and the structure of family and exerts pressures upon it for good o that must be considered later. Even when change of life, which is biologically condition makes its appearance in the course of time h it is experienced is socially influenced. L adolescence, it may become a period of storm s stress, or, on the other hand, the prelude to a c tented retirement with enhanced powers of joyment both sexual and esthetic; its connect with cultural factors is demonstrated even wit the bounds of our own country where seri depressive states in middle age are much co

oner in the more puritanical north than in the ore permissive south.

OLD AGE.

ological Factors.

Anyone can see that not only do the signs of old e come on at very varying times, being some- nes relatively early and in other cases hardly pparent at all even in advanced years, but also at, when the signs do come, they assume a form hich is the same for all peoples and at all places. his is because old age, like puberty and the change life but even more so, is brought about by sically biological factors. These include glan- dular changes, though the most obvious results senility arise from a deterioration of the sub- ance of the brain caused either by a primary generation of the cells in the nervous tissues or a condary degeneration which produces the same sult by reducing their blood supply when ageing teries become hardened and narrow. The ef- cts of these changes can be summarised by saying at senile deterioration leads in varying degrees memory changes such that memory for recent vents is poor whilst that for long past events is ually retained or even emphasised and dwelt on; at the individual tends to become emotionally nstable and, for example, more easily moved to ears; and that there may be apparent changes in ersonality.

ocial Influences.

These changes are more apparent than real, for hat actually happens is that, with the deteriora- on of the higher centres of control, features such s jealousy, greed, or meanness, which have itherto been kept under control, are released. n other words, the senile person 'becomes him- lf, only more so'. But even in the presence of such changes as are clearly due to biological factors, social influences are very much in evidence —for example, in our form of society where old people are often regarded as a problem or a nuisance, it is hardly surprising that they tend to become suspicious, irritable, and self-centred.

Technical change has brought a situation in which, unlike that in the old peasant or agrarian community, old people and schoolchildren, up to quite a later age, are unproductive. Whereas in the changing rural communities of today and even in the old East End of London, the grandparents played an important part in the life of the com- munity, looking after the grandchildren whilst their mother and father were at work, advising their own children about matters in which their long life had given them the experience to guide, and acting as the respected elders of the village or suburban group, they now find themselves un- wanted. The younger generation is moved out to satellite towns whilst the old people are left be- hind, alone and lost in a world they no longer understand. What seemed to be eternal verities have gone, and these are needs that even the best treatment in an old people's home cannot satisfy.

Here is another clear example of a biological pro- blem which is also a personal one and at the same time very much a social one to be solved not by charity and misplaced sympathy but by the under- standing that comes from a combination of science and caring which are more closely related than is always realised. As Leonardo da Vinci wrote in his 'Treatise on Painting': "In truth great love springs from great knowledge of the beloved ob- ject, and if you know it but little you will be able to love it only a little or not at all." Or in the langu- age of Freud, even the most abstract study of the universe requires that the object of our study should be invested with the love we have projected upon it; when hate is projected hate is what is reflected back and we understand nothing.

II. SOCIETY

1. SOCIETY AND CULTURE.

A society is a more or less permanent group of eople living together and sharing a common way f life and common attitudes and beliefs. Its ulture is the name given to this way of life, and he term *physical culture* refers to objects such as eapons, bowls, art, and in more complex ocieties, an elaborate technology. The people ho make a special study of different cultures are nown as social anthropologists and when they rst began to take their work seriously and carry ut field studies by living among the people they ere studying, it was natural that they should hoose primitive tribes as being the most con- enient because (at any rate at that time, from he beginning of the present century to just before he last war) there were many of these primitive roups which had lived in comparative isolation nd therefore showed the culture in an almost nadulterated form. The culture had remained nchanged for many centuries, and among these eople the social structure was much more rigid and asily defined than in the larger and more complex ndustrial societies. Nowadays, however, a ocial anthropologist may study any sort of ulture, for example, a Yorkshire mining com- munity, or a working-class community such as agenham, a study which is mentioned in Part III.

Basic Personality Structure of a Society.

Enough has already been said to show that there are great variations among different cultures as to what people consider 'normal' behaviour and the different roles its members ought to play in rela- tion to the rest. Culture not only imposes general beliefs which are expected to be shared by all members of a society (for example, its religion and mythology or its economic and political system) but defines the part men and women must take in the division of labour or rearing the family to- gether with accepted methods of doing so, and the rules children must follow in dealing with each other and their parents or elders. This results in what has been described as the 'basic personality structure' of a society, the blueprint for parents to adopt when bringing up their children.

Studies of Primitive Societies.

A brief glance at some of these various cultural ideals in primitive societies is necessary because they are of great practical interest to psychologists and psychiatrists to whom they have given an entirely different view of the potentialities of 'human nature' and caused the psychiatrist, in particular, to re-think what he means when he talks about 'normality', and even what he means by 'mental disease'. Thus the great majority of psychiatrists up to the late nineteenth century, and a certain number at the present day, have taken the view that mental disease is brain disease but this belief requires considerable modification if one finds that serious depression leading to suicide is totally unknown in some communities, that people in one tribal group show many of the symptoms of what in Europe would be regarded as schizophrenia, that the neurosis known as 'con- version hysteria' is commoner in technically backward parts of the world and, even in Europe, begins to disappear as technology advances. Similarly, those who have always supposed that certain behaviour is typical of women and that women are socially and intellectually inferior to men because of their allegedly innate physical weakness and their peculiar glandular structure, will have to reconsider their belief when they find that in some societies women are the dominant sex.

The Researches of Ruth Benedict and Margaret Mead.

Two American anthropologists, Ruth Benedict and Margaret Mead (who has already been men- tioned in relation to her study of adolescence in Samoa), began in the 1930s to study various primi- tive tribes and the differences in basic personality structure that they discovered were striking. To take a few examples: among neighbouring tribes in New Guinea Mead found the following dif- ferences in sexual attitudes. One tribe, the Arapesh, had as its ideal the mild responsive man married to the mild responsive woman; another, the Mundugumor, valued the violent aggressive

man and the corresponding aggressive woman—in fact, aggressiveness was so strong a feature of this tribe that literally every man hated and feared every other man and the only possible relationship between two men was one mediated by a woman; a third tribe, the Tshambuli, showed a complete reversal of the sexual attitudes regarded by us as 'normal' with the husband the mild submissive partner who sat at home dressing himself up and applying cosmetics whilst the wife was impersonal, dominant, and managing, doing most of the work outside the home. Benedict found that the Zuni Indians of New Mexico had such a distaste for aggression or even self-assertion that the polite thing to do was to try to lose at competitive games, and leaders could only be elected by locking up some of the nastier members of the group until they broke down and agreed to act as chiefs; once elected, they were regarded with contempt and, at the least sign of self-assertion, would be hung up by their thumbs until they confessed and promised not to behave in that way again. The Arapesh, too, are so unaggressive that the sign of anyone in a rage shocks them as much as any discussion of sex shocked our Victorian forebears. The Dobu of New Guinea live in such a state of persecutory suspicion that a Western psychiatrist would unhesitatingly diagnose them as paranoiacs just as he might diagnose a typical Balinese as schizophrenic, and whilst the Western industrialist tries to acquire wealth, the Kwakiutl Indians of Puget Sound hold ceremonies at which the men compete to discover who can destroy the greatest amount of money in the shortest possible time.

Many societies, like the Greeks of classical times, have valued homosexuality as being a more spiritual form of love than sexual relations with women who exist only to do domestic work and bear children. In the words of Benedict, we have come to realise that "most of these organisations of personality that seem to us most incontrovertibly abnormal, have been used by different civilisations in the very foundations of their institutional life. Conversely, the most valued traits of our normal individuals have been looked upon in differently organised cultures as abnormal. Normality, in short, within a very wide range, is culturally defined."

Cultural Change.

Two important questions arise from these observations, the first is how these various cultures arose and took the particular form they did, the second is the problem of what makes cultures change. The answer to the first question is fairly simple: it is that each culture is a way of life suited to a particular group with certain historical traditions and adapted to a specific physical environment. It is both unconsciously and deliberately passed on from one generation to the next by specific methods of child rearing. "Systems of child training", writes Erikson, "represent unconscious attempts at creating out of human raw material that configuration of attitudes which is (or once was) the optimum under the tribe's particular natural conditions and economic-historic necessities."

As will be seen in more detail later, the basic personality structure of Western Europe completely changed about the time of the Renaissance from a state of affairs in which conformity and a static social structure was the ideal to one which valued the most extreme expressions of individualism, personal aggrandisement, acquisitiveness, and social mobility. No living things are so variable as human beings and, though the existence of their innate needs explains why they *initiate* certain actions (*e.g.*, why they want to eat, drink, or obtain sexual satisfaction), it does not in any way explain *how* they do these things, why they sometimes do them when they do not wish to, or do not do them when they do wish to; biology becomes subservient to culture and even the most pressing physical needs may become secondary to social needs. Thus in an American town during the depression of the early 1930s, purchases of food declined markedly whilst petrol sales remained at the normal level—obviously the social prestige associated with running a car was more important to many impoverished citizens than having regular and satisfying meals.

Causes of Technical Backwardness.

Whilst such societies as the primitive tribes have been discussing have shown little chan over many centuries, the technically advanc societies are subject to ever-accelerating soc change and, of course, under the impact of Weste technology, even the primitive communities beginning to enter a new state of development. has often been thought that the backwardness certain peoples was due to some sort of inna inferiority, but the reasons for their appare backwardness are quite unrelated to any su factors. First, the use of this term is, to so degree, a value judgment—for who is to s whether our society with all its many hum problems is 'superior' or not to simpler societ where, for example, suicide and war may be conceivable? Second, two of the reasons technical backwardness are quite evident: th the Eskimos never entered an iron age for the s reason that they had no iron, and brains are little avail without the appropriate material co ditions to work on; furthermore, until rece times, few of these peoples ever had the stimul of meeting more complex civilisations. We o selves lived in a state of comparative backwa ness until we were invaded and occupied by t Romans. Third, there may be some truth Arnold Toynbee's suggestion that cultures ne some environmental stimulus to set them movi on the path to progress, and it is of interest note that nearly all the great civilisations ha developed in temperate lands where nature w not so harsh as to prevent any elaborate cult from arising nor so lavish as to make such tempts unnecessary.

Technological Change.

Primarily, says W. F. Ogburn of Chicago, "the cause of social change is the making of inventic mechanical or otherwise, and secondarily, t diffusion of inventions already made." Whi new *discoveries* are by their very nature qu original, *e.g.*, the discovery of how to make bron (the first alloy known to man) from its constitue metals of copper and tin, was something entir novel in man's history, new *inventions* are for t most part a combination of old elements—that they are dependent upon already-known pr ciples. It follows that the more of such eleme or principles existing in a particular culture t greater will be the number of possible new ventions. So although a simple kind of stea engine was devised by Hero of Alexandria A.D. 62) nearly two thousand years ago, it was p practical use because before the steam-engi of the eighteenth century could be produced it w necessary to know about new ways of treating ir to make it harder, the principle of transmitti power from shaft to shaft and from one directi to another which involves knowledge of the tooth wheel or gear, the idea of vehicles travelling rails, and many other elements. Today, ever complicated piece of machinery such as t electronic computer was readily put together utilising and recombining a large number of e ments and principles already known. Techni progress moves at an ever-increasing rate for j this reason, and as Ogburn has pointed out mater culture grows according to the exponential pr ciple, *i.e.*, like compound interest.

The Social Effects of Technical Change.

Since culture is an attempt to adjust to a pa cular environment which is now almost entir of our own making, it follows that the culture modern society is an attempt to adjust to our ma made environment and reflects this material ba ground, and also that, since the pace of develc ment is rapidly increasing, adjustment becon ever more difficult. This has been noted alrea in the gulf of understanding between generatio for even the most modern youth is barely adjusti to the changes of ten years earlier. The situati is very similar to that described by Karl Ma who whatever one may think of his econor theories, was one of the greatest sociologists w ever lived. Marx described a substructure *Unterbau* which he believed to be the econor system of a society, and pointed out that upon t is built the religious attitudes, ethics, laws, a

nstitutions which form the *Oberbau* or superstructure of society. (*See* J27). In fact, the less a body of thought is subject to objective verification, the more is it likely to reflect the substructure of society which modern sociologists regard as its echnology. Whilst science is comparatively culture-free, existing religious attitudes or philosophical systems or ethical beliefs are very strongly influenced in this way; for example, the Reformation (J38) was not brought about by Luther's distaste for the corruption of Rome, since movements dating back to the thirteenth century or earlier (the Waldenses (J45), the Albigenses (J2), and that led by Wyclif in England) had felt just the same—it happened *at that time* because Luther's ideas fitted in very well with new individualistic attitudes resulting from the early stirrings of the industrial revolution and German nationalism. Again, slavery would have been abolished in America even if William Lloyd Garrison had never been born and *Uncle Tom's Cabin* had never been written; slavery disappeared because it was becoming useless as a means of production, just as it had previously been supported by moralists so long as it was useful. Reformers need to learn that one can rarely start a trend without pre-existing foundations, frequently accelerate one that already exists, but never reverse trends already moving in a particular direction in response to environmental pressures.

The Stages of Cultural Change.

The development from technical changes to changes in the ideological superstructure takes place in four stages:

(1) The material invention or discovery.

(2) Changes in the economic and social structure.

(3) Changes in the other parts of the social structure.

(4) Change in cultural attitudes and popular ideology.

Let us take as an example the influence of the steam-engine on woman's position in society. First, the various types of steam-engine led to the development of more efficient and specialised power-driven machinery on the railroads, in the factory, and ultimately in the home; transport is made easier and therefore cities grow larger, industrial work is made lighter, and house-work less onerous. As a result of this the greater physical strength of men becomes less important in many forms of work and women become as efficient as men over a wider field; they are increasingly employed in industry, work becomes separated from home, and gradually there arises an improved standard of living, increased consumption, and a more easy-going attitude to life.

Changes in other parts of the social structure develop more slowly: the modern family is no longer an economic unit as in the agrarian society, and it is losing its rigid social control over its individual members whilst, as Folsom puts it, "elaborating other functions, most important of which is the more complete satisfaction of the love-wish, both with regard to marital and parent–child love". There is no longer one single accepted family-pattern, the patriarchal family, but wide variations from the mother-centred family to the egalitarian family and even the filiocentric family, so that power is no longer centred exclusively upon the father and the family is becoming more democratic. Of course, all these developments arose not from any single cause but were helped along by such other technical inventions as gas and subsequently electric lighting in the streets and home, the wider knowledge and use of contraceptives, and the mass media which (in one of their aspects) led to a wider and faster spreading of knowledge and a levelling in cultural standards.

Cultural Lag.

Traditional attitudes and old ways of thinking, however, tend to persist much longer, largely because they are identified with values which are very deep-seated and any attempt to modify these is likely to be described as "a lowering of moral standards" or in such terms as "the moral crisis of our time". Of course, there is a moral crisis, but it is due not to change but precisely to the failure to change; it is caused by the 'cultural lag' between old attitudes and a new environment. Thus the so-called 'equality of the sexes' to which all but the least-enlightened pay lip-service is more nominal than real; for what has happened is that, whilst women have gained many new functions, they have lost few of their old ones. The girl who comes back from work at the factory is still expected to do some of the housework whilst her brother is not. There is even an attempt to drag women back to their more 'feminine' role with the appeal of cosmetics, fashion, and home-decoration advertising; papers of good standing intended for both sexes nevertheless have a special section for women as though they were social oddities in a way that men are not; and there is the tremendous number of women's magazines catering for all that is most infantile and written in a kind of baby-talk, stories of how the heroine succeeds in marrying her boss, columns dealing with how to dress, solving one's love-problems, and the rest. As Dr. Viola Klein says, the state of women at the present time is characterised by a dilemma, which is another of the many conflicts inherent in our present cultural situation. "It results from the contrast between a materially changed situation and the simultaneous survival of traditional ideologies and attitudes." One has only to think of the fuss made by many men teachers at any suggestion that women should get equal pay for equal work, to see how true this statement is.

Cultural Change in the Underdeveloped Countries.

In the more technically backward societies, the impact of industrialisation and new mass-production techniques has been even more dramatic. Drucker has shown how "the sweep of mass-production technology is undermining and exploding societies and civilisations which have no resistance to the new forces, no background or habit-pattern of industrial life to cushion the shock. In China the mass-production principle, swept into the hinterland from the coastal cities by the forced migration of industries during the Japanese invasion, is destroying the world's oldest and hitherto its stablest institution: the Chinese family. In India industrialisation has begun to corrode the Hindu caste system: ritual restrictions on proximity and intercourse between castes simply cannot be maintained under factory conditions. In America the Old South, hitherto least touched by industry and still living in the ruins of its ante-bellum order is speedily being 'tractored off'. Indeed, conversion of the Southern farm into a rural assembly-line seems on the verge of 'solving' the Southern race problem in a manner never dreamed of by either Southern Liberal or Southern Reactionary: by pushing the Negro off the land into the industrial cities."

Whilst we in Britain have had ample time to adjust to the results of the industrial revolution and have not yet succeeded in completely doing so, the danger in these new societies is that what took more than two centuries here is being compressed into a matter of a few years with a consequent risk of serious conflict and the uprooting of old values with nothing to take their place. Unless social scientists work alongside technicians to ensure that social change is smooth, the persistence of traditional attitudes against a new material background may have dangerous results.

Since the end of the last war the introduction of modern medicine to Ceylon has halved the death-rate, largely by virtually wiping out malaria with drugs and DDT; it was reduced from 22 to 11 per thousand in less than ten years—but the birth-rate remains the same and, at the present rate, the population will more than double every 25 years. The failure to make psychological adjustments to situations of this sort has resulted in the great benefits made possible by science in the form of better health, better nutrition and higher standards of living being nullified as quickly as they are being developed.

All over the world man's greed has led, in the words of Julian Huxley, to the despoiling of nature at an appalling rate. "Wildlife is being exterminated; forests are being cut down, mountains gashed by hydroelectric projects, wildernesses plastered with mine shafts and tourist camps,

fields and meadows stripped away for roads and airports." Processes such as these are not planned with a view to the greater benefit of people in general but motivated by a blind and stupid acquisitiveness.

2. THE MODERN SOCIETY.

The large-scale modern society differs from the primitive societies, first investigated, in some important respects which will now be discussed.

The Social Structure: Sub-cultures.

The social structure of modern society is much more complex due to the existence of class differences, regional groupings, and different racial and religious or political groups within the national boundaries. These are described as sub-cultures and require to be considered separately against the overall culture of the state. Thus, though all Britons share some attitudes in common which can be described as the national character, a Roman Catholic Briton does not share all the values of a Protestant one; a middle-class Briton has very different attitudes to many things compared with a working-class one; and a Yorkshireman differs culturally from a Welshman. It is necessary to understand this when we are trying to unravel the causes of racial disturbances, industrial unrest, and other problems in which there are two opposed groups failing to communicate because they are simply not talking the same language and see the same events in a totally different light.

We must repeat, too, that national character is not fixed nor is it innate, but like other constellations of traits has social and historical roots. In spite of the complexity of these national groups more or less successful attempts have been made to understand their overall culture: Mead and Gorer have written studies of the American national character, Gorer of the Greater Russians, and Benedict of the Japanese. The usefulness of these studies is shown by the fact that Benedict was able successfully to predict how the Japanese would react to defeat and occupation at the end of the last war. Much of the American national character can be explained in terms of the rejection of the alien father by the children of first-generation immigrants and the fact that most American males are almost entirely reared by women from the possessive mother whose cult has been described as 'momism' to school education which is carried out largely by women teachers. Hence the American suspicion of 'foreigners', their rejection of Europe towards which many have a love–hate relationship, their constant affirmation of manliness and being 'red-blooded Americans' and their terror of homosexuality—the latter attitudes arising from a deep-seated fear of the sometimes overwhelming females who reared them causing a need constantly to affirm their maleness, and the already-noted fact that boys brought up mainly by women often develop latent or overt homosexual tendencies against which they attempt to defend themselves. Jess Stearn's book *The Sixth Man* which asserts that "one out of every six men in America is a homosexual" demonstrates this fear to an almost paranoiac degree and, although almost entirely nonsensical, became a best-seller showing how widespread is this anxiety in the United States.

Rapid Social Change and Social Status.

Another respect in which modern society differs from primitive societies is the rapidity of social change which leads to the discrepancy between old traditions and present realities with results which have already been discussed. In a society of rapid change social status is not only subject to fluctuation as the individual moves up or down a scale created by extreme social mobility, but quite often status is not (as it is in more primitive groups) very clearly defined, and this leads to feelings of insecurity. Since social status is a kind of transference of the child's need for maternal approval towards the need for the approval of society in later life, we can say that the desire for status is one of the most fundamental of human drives and its absence or loss is a common precipitating factor in neurosis.

In the first part of this section we saw how many of the individual's attitudes are derived from th groups to which he belongs, and it is these whi are his main source of status, from the sma primary, informal groups such as the family, th play-group, the work-group, the group of villa elders, the group of housewives who regular meet for a cup of coffee, to the large and mo impersonal secondary institutions which conf formal status, *e.g.*, the army, the profession industry, the churches, and so on. If the prima groups break up, status is in peril.

The Sick Society Concept.

Now, in the view of some authorities, this is ju what is happening. The old primary groupin are allegedly disintegrating in what has becon a mass society, and the family, the working grou the village council, are being replaced by hu anonymous bodies in relation to which person status, useful function, and individual significan are lost. It is further claimed that more than a previous society ours is one which persistent stimulates people's desires without being able t satisfy them, and that it is based on conflictin ideals which the individual finds it impossible t reconcile. Whilst accepting the two latter stat ments with reservations, the present writer, fo reasons to be discussed elsewhere, does not whol accept the first. Nevertheless it is obvious th many supposedly personal conflicts are really in posed upon us by society, and the psychoanaly Karen Horney believed that the conflicts found the neuroses are simply a microcosm of soci conflicts. From such considerations as these ha arisen the concept of the 'sick society', elaborate on by Halliday in this country and Frank America, which suggests that since all our mo pressing problems are simply facets of a mo fundamental problem lying at the very heart modern society, they can be dealt with co structively only at the social level. Frank e presses his views as follows: "Instead of thinkin of a multiplicity of so-called social problems, eac demanding special attention and a differe remedy, we can view all of them as differe symptoms of the same disease. If, for exampl we would regard crime, mental disorders, fami disorganisation, juvenile delinquency, prostituti and sex offenses, and much that now passes as th result of pathological processes (for exampl gastric ulcer) as evidence not of individual wicke ness, incompetence, perversity, or pathology, b as human reactions to cultural disintegration, forward step would be taken." This is tant mount to saying—*as* is quite true—that malar is most suitably dealt with by killing mosquito with DDT or typhoid fever by ensuring a pu water supply, but it does not alter the fact th once individual cases have been infected, th physician must have recourse to quinine a penicillin. Certainly we are made what we a by social pressures, but as individuals we have learn to live with these pressures and in wh follows an attempt will be made to show th individual responsibility must still play a part a that we personally can do something to hel ourselves.

The sick society concept is both true and usef and, practically speaking, it does three things:

(1) It makes us realise that it is n profitable to try to help people by blamin them and that an additional reason for n doing so is that society (which is anoth name for ourselves) has played some part making them what they are. One has on to think of the many moralists who ha supported prostitution in the past because upheld the 'sanctity' of the family, mai tained the 'purity' of the middle-class gi and reduced what might otherwise have r suited in emotional tensions.

(2) It makes us realise that our ow problems, if often peculiar, are never unique

(3) It helps not only in discovering wh these problems are but, by revealing the social background, enables us to see the more constructively, less uncharitably, a points to possible solutions.

If we recall Jung's case of the Quaker who cou not imagine that he had ever done anything wron

et whose son became a thief and his daughter a rostitute, we may see therein a parable showing ow the respectable members of society are not ulitless of creating juvenile delinquency and rostitution because those who engage in these ctivities represent the dark aspects of society nd act as our scapegoats. In a perfectly real ense, we are enabled to remain 'good' because ney are 'bad'.

3. THE FAMILY.

amily Conflicts.

The original family was the extended family of grarian communities which included not only oth pairs of grandparents but also various uncles nd aunts and assorted relatives. It was an conomic unit in which throughout life each ember had a useful part to play; moreover eing large, family tensions were less prolonged if ften no less acute than in the family of today.

The modern family is usually small because ildren, until they go to work, and the old who ave finished work, are economic liabilities, ut this very smallness leads to more intense nd chronic disagreements, the more obvious ources of which have already been mentioned: alousies between children, parental conflicts, onflicts between parents and children as the latter ry to assert their independence, and between randparents, who feel useless and unwanted, nd their children and grandchildren. Other ources of difficulty arising from without the mily are modern society's obsession with comercial sex which incessantly stimulates desire hilst conventional morals deny it outlet, and the o less stupid obsession with the achievement of omplete sexual satisfaction as a necessity for a appy marriage. Working mothers in addition to heir other worries are told by reputable psychiaists that by going out to work they are turning heir children into potential delinquents; many nen still refuse to recognise the changing role of omen in society and attempt to reverse the trend y reverting to the 'baby doll' image of womanood; the 'housebound housewife' feels the boredom that only increases with affluence. All these re real problems yet it is undoubtedly true that at o time has the British family been so stable and o mature in its relationships. We hear about the ailures because their are newsworthy and most idely discussed by experts and, as Michael oung and Peter Willmott have shown in their tudy of the family in Bethnal Green, all that is ritten about broken marriages, juvenile deinquency, child neglect, and problem families as "created an impression that working-class amilies are disunited, unsocial, and unhappy".

he Present Status of the Family.

We have no space to discuss the fallacies inolved in this belief, but perhaps this is best done y quoting from two of the most detailed acounts of current attitudes towards the family: he study mentioned above on working-class ttitudes, *Family and Kinship in East London*, nd Gorer's more inclusive book, *Exploring English Character*. Of the modern working-class amily Young and Willmott write: "(Our) impressions suggest that the style of working-lass family is fast disappearing . . . in place of he old comes a new kind of companionship between man and woman, reflecting the rise in tatus of the young wife and children which is one f the great transformations of our time. There s now a nearer approach to equality between the exes and, though each has a peculiar role, its oundaries are no longer so rigidly defined nor is t performed without consultation."

In a survey which covered all classes in England, orer discovered that half the married population f the country have had no sexual relationships ither before or after marriage with anyone else ut their spouse, and continues: "What seems o me most noteworthy is the high seriousness ith which the great majority of English people pproach and regard marriage. Whether prearital experience is advocated or reprobated, the ffect on the future marriage is the preponderating onsideration. Secondly, the high valuation put n virginity for both sexes is remarkable and should suspect specifically English." Neithe. sex pays any appreciable heed to the æsthetic qualities of the other, and when asked to give their opinions on the factors making for happiness in marriage most people mentioned "give and take, understanding, love, mutual trust, equanimity, sexual compatibility, comradeship, a decent income, mutual interests, happy home life, and no money difficulties." One of the biggest surprises in this study was the small number of people who thought that infidelity was a significant cause of marital unhappiness, and most believed that adultery "should not terminate the marriage (if that can possibly be avoided) and does not justify the wronged spouse in adopting violent or aggressive behaviour". This view was accepted by more than half the men and nearly three-quarters of the women. Furthermore, as Gorer says, "there is at least as much tendency to blame oneself for a spouse's dereliction as to blame or punish the offending spouse." He suggests that such attitudes imply a relatively low valuation of 'love' and a very high estimation of the institution of marriage, and concludes: "(I) have I hope illustrated the great importance for English men and women of the institution of marriage and the seriousness with which they consider it. It is marriage itself which is important, not, I think, love or sexual gratification; and marriage is living together, making a home together, making a life together, and raising children. Perhaps even more for Englishmen than for English women, parenthood is the greatest joy and greatest responsibility of adult life."

The Married Couple.

There is therefore ample reason to suppose that most married couples in this country are reasonably satisfied with their own lot even if the new society has also given rise to problems. Here we are going to discuss some of those involved in the husband–wife relationship, and it is convenient to do so under the three headings of personal relationships, sex, and work. But before going into details, it is important to consider what exactly is meant by 'happiness', the goal towards which most people seem to be so fervently striving. Indeed, the word 'striving' sums up very clearly what 'happiness' implies: it is, as one psychologist has said, "the state of going someplace". A person is happy when he or she has certain goals which they are on the way towards achieving, no matter how slowly or with what difficulty. Happiness means movement towards, and the pleasure is in the moving rather than in the achieving—which sometimes leads to rather a disappointment. When the philosopher Schopenhauer said that the lot of man must inevitably be a wretched one because he could only be happy in relation to a previous state of comparative unhappiness, he was perhaps being unduly pessimistic but at the same time he was expressing a profound truth: that there is no absolute happiness, but only happiness *in relation to how we felt before*. Thus a crust to a starving man provides more pleasure than another million pounds to a millionaire.

This was strikingly illustrated in a social survey in the United States where many people of all income-groups were asked by what percentage their annual income would require to be increased in order to make them entirely satisfied. The result showed that *all* income-groups produced practically the same figure; both the fifty-dollar-a-week man and the five-hundred-a-week man agreed that an increase of 25 per cent would be adequate. People talk glibly of the 'essentials of life' or the 'basic essentials', but there is, of course, no such thing; what we already have are the basic essentials for us and we usually want a little more. No amount of affluence can make us happy because happiness is a state of striving for more—it may be more money, more household appliances, more children, more rooms and space or more knowledge and virtue, but it is always more of something. Happiness is quite different from contentment which is a state of not wanting, of being satisfied with what we already have, and it is probable that static communities such as the so-called 'backward' countries or the Europe of the Middle Ages contain more contented people because they can move neither up nor down the

social scale nor very easily change their position geographically. Doctors and psychiatrists see plenty of people who 'only' want happiness when what they really mean is that they want peace of mind (which is contentment) or that they want happiness but are not prepared to accept that, since this involves striving, it also means the acceptance of much pain and frustration and hard work. Those who think that happiness is something they are *entitled* to—as the Welfare State or the Affluent Society often leads them to believe—had better think again; the *means* to contentment, yes, the *right* to happiness, no. Men or women who set their aim far above what they are humanly likely to achieve should remember the equation which reads: expectation minus realisation equals neurosis.

Personal Relationships in Marriage.

Now this applies with particular force to marriage; for those who have been dazzled by silly romantic stories or commercial advertising into thinking that they are entering a state of undiluted bliss, and, if that fails, there is always a new washing machine to create happiness by lightening their labour, are living in a fool's paradise. Marriage is a constant struggle throughout life to become more mature, better adjusted to one's partner, more tolerant, but above all it is a constant process of education in human relationships. Maturity has already been defined as a state in which relationships are neither self-denying nor denying the rights of others but based on mutual acceptance and respect, and this is the key to satisfaction in marriage. Nobody is more pathetic and in the end, more distasteful, than the mother who is continually telling her husband or her children or her own mother how she has 'sacrificed herself' for them; for in doing so she is either demonstrating her own insincerity (since what one gives up *willingly* for the sake of others is not a sacrifice any more than it is a sacrifice for a man to give up his game of darts at the local in order to give more attention to his pigeons or the new baby which he finds much more interesting), or revealing her masochism, her stupidity, and, almost always, her malice. What she really wants is to make the others feel dependent on her, to inflate her own ego, show her spite, or cause them to feel guilty. Nobody can usefully help by relinquishing personal rights *unwillingly and unnecessarily* for the supposed rights of others, *because love for humanity begins with genuine self-love and self-respect.* In other words, whilst situations frequently arise in which one must consciously and deliberately give up some personal rights, this is totally different from the case of the mother who keeps on harping about her total self-sacrifice because, as we have seen, her action is not motivated by the desire to be helpful but rather by a neurotic compulsion to feel 'put upon'. Now this kind of behaviour leads to a vicious circle; for the woman's self-induced limitation of her rights as a person naturally makes her increasingly resentful of those who are felt to be responsible for her frustrations and since this resentment must remain unconscious (because it would clash with her self-picture of martyrdom), she can only respond by making herself even more of a martyr in ways which other people will easily recognise to be motivated by malice and spite. She is not only tormenting herself, but everybody else in her family.

The Housebound Housewife.

In order to distinguish between the normal and the neurotic giving up of individual rights, let us take an example from the so-called 'housebound housewife'. Here is a woman who feels lonely and depressed for various reasons discussed elsewhere but, in general, because she has been used to company before marriage and feels isolated when tied to the home looking after young children, or perhaps because she is ambitious and feels that her present position does not give sufficient scope for her abilities. There is nothing surprising or reprehensible about feeling this way in the circumstances, and the normal approach is that she should begin by being fully aware of the total situation and honest about her feelings in relation to it, subsequently doing something practical to alter the actual situation or herself.

Three solutions immediately present themselves:

(1) After discussion with the other members of the family, and having made suitable arrangements for the children, decide that part- or full-time job is the answer.

(2) To look around for work, studies, interests, or hobbies that can be carried out in the home to alleviate boredom and possibly prepare the path for more interesting work in the future.

(3) To accept the situation and, after careful thought, change her own attitude towards it, arguing, for example, that looking after the home and her young family should be a rewarding and important period of life which will all too soon be over leaving her free to do as she pleases.

At the other extreme is the neurotic solution which occurs with the type of woman who refuses to face the situation constructively and thinks of it in 'moral' terms, denying that she wants to leave the home at all or that the children tie her down and limit her freedom of movement; she is so 'self-sacrificing' that she does not realise that normal love is always ambivalent in which love and anger or hate are parts of the mixture. Her world is composed of black and white, not as is the real world of varying shades of grey. This may lead to the not uncommon type of neurosis which has as its main symptom the fear of leaving the house even for a single moment, because as was seen earlier a conscious fear is often the expression of an unconscious wish. Immediately she puts her foot outside the door or attempts to cross the street, she is suddenly overwhelmed by attacks of sheer panic. What are the consequences of this 'solution'? First, her neurosis prevents her doing what she really wants but refuses to admit to wanting; second, she is punishing herself for her 'wicked' desires but, being frustrated, her unconscious resentment increases and with it her conscious anxiety; third, she is punishing the rest of the family by being 'ill', becoming a professional martyr probably requiring psychiatric treatment, and fills them with guilt both by snide remarks inferring that her condition is caused by overwork, and by coldness towards them, or perhaps by outbursts of irrational and uncontrollable rage. Certainly she is frustrated, but the cause of the frustration lies not in her objective surroundings but in the way she interprets them.

Truth and Honesty.

Normality in personal relationships can be judged by the degree to which one is aware of the objective situation and able to appreciate the nature of unconscious factors motivating behaviour. So far as humanly possible, one is true to one's own nature and truthful in most circumstances. The more mature a married couple are, the more will it be possible for them to be completely truthful with each other but since no one is completely mature, it is not always wise to tell the truth regardless of circumstance because those who do so are not always motivated by a desire for truth but by unconscious motives ranging from the need to purge personal feelings of guilt without the least regard for the feelings of others to the desire to wound. One of the commonest questions appearing in the personal problems columns of women's magazines is whether some sexual peccadillo in the individual's past should be revealed to the husband, to which (unless the act had repercussions which are still having an effect) the simple answer is: certainly not. Assuming that the person is moved to tell because of continuing feelings of guilt or shame then we can only say:

(1) that such feelings, like those of so-called self-sacrifice, are very often a sign of a concealed but overweening conceit demonstrating the individual's own satisfaction with a tender conscience he (or she) must possess

(2) that the correct solution to guilt is surely not to permit what cannot be undone to spoil the present—which is a much more practical reason for feeling guilty—but

resolve to learn from experience and employ it in avoiding similar mistakes in the future;

(3) that if the act must be confessed, then the best person to confess to is someone who is not emotionally involved, such as a priest, physician, psychiatrist or even a sympathetic, reliable and impartial friend;

(4) that the woman (or man) concerned should consider very seriously the *real* motives lying beneath the need to confess, which, as suggested above, are not infrequently the desire to attract attention or even to wound the other partner.

The only circumstances in which these rules ould not always apply are those in which the rong can still be undone or partly undone in hich case the individual's duty is clear, or those hr which news of the act is likely to reach the ears of the partner sooner or later from some other urce, when it is usually wisest to consider making clean breast of it (though, even then, it would be ise to be sure of one's correct estimation of the bjective situation and the probable response of he other).

nowing Oneself.

The fundamental rules for close personal re-tionships within or without marriage are: nature affection (which has already been defined), ncerity, as much honesty as is wise judged by he criteria above and, most of all, self-knowledge. ne of the ways in which we can become more lf-aware is by observing not merely what we elieve to be our conscious motives, but the con-quences of our actions. If a husband or wife esolves to be pleasant and friendly when the ther returns from work yet every time the even-g is spent in constant bickering, then there must e some underlying resentment which it would be ore helpful to bring out into the open and discuss ankly, than to continue making futile resolutions nat are never kept. Any particular emotion or ype of event always seems to keep on recurring; or example, if in all our relationships we in-ariably end up by feeling 'put upon', if we can ever maintain a friendship for long, if a woman ays that her dearest wish is to get married yet he fails to do so, if one allegedly loves a child et is constantly losing one's temper with it, if ther people always seem unfriendly and shop ssistants rude, if we are frequently depressed or nxious without apparent cause, then the causes must be sought inside ourselves, since it is im-ossible that the environment is always to blame. The woman who believes that she wants to get narried yet never finds the 'right' man, has ffairs which invariably come to an end, or some-ow inevitably seems to fall in love with un-uitable people—married men, confirmed bache-ors, or those with latent homosexual tendencies, s obviously not being quite truthful with herself. Perhaps she wants to marry but fears the loss of er independence, perhaps she feels incapable of any close relationship with another, or perhaps she s afraid of sex and motherhood; for the fact is hat even the plainest woman can get married if he wishes, and whether one falls in love or not depends less on that person's objective qualities than on our own deepest needs. In other words, a person who really wants love and marriage can't help falling in love. If we are constantly quarrelling with a loved one, it is because we refuse to admit that in certain respects we also resent him, and it is sensible to recall Dr. Winnicott's dictum that the danger arises, not from aggressive-ness in itself, but from the repression of personal aggressiveness in individuals. Or, as the poet Blake expressed it:

> "I was angry with my friend,
> I told my wrath, the wrath did end;
> I was angry with my foe,
> I told it not, the wrath did grow."

Indeed, as the poem continues, the wrath was lovingly nurtured and increased until it finally ended in murder. Anger and aggression must often be consciously suppressed in ordinary social situations in which emotion would be inappropriate, but in personal relationships it should never be repressed but admitted and talked out.

Sexual Relationships.

The belief so assiduously spread by specialists during the 1930s that complete sexual satisfaction in both partners is not only necessary but inevitably results in a happy married life turned the truth upside down; for the fact is that, in general, a happy married life based on love and respect is the cause rather than the effect of good sexual relations. Every psychiatrist has seen many cases of marriages in which physical relations were perfect and yet the marriage ended in divorce, and even more in which the sexual life was not wholly satisfactory but the marriage as a whole was.

The causes of sexual difficulties are rarely anatomical but have their origin in unconscious fears, guilt, and sometimes in ignorance. But ignorance is not as common a cause as used to be thought, not because it does not exist, but because a genuinely loving couple will find it easy in the course of time to make adjustments and discover for themselves. The bogey set up by these foolish 'experts' that women who do not always achieve complete satisfaction are in some way abnormal may have some sort of theoretical background, but it has very little relationship to the real state of affairs in which a majority of women may achieve orgasm fairly frequently, only occasionally, or not at all throughout their married life. Men who are always impotent are not very common and need medical or psychiatric help, but for women the state of affairs is quite different. Most men experience sexual desire initially as a physical need like hunger, whilst women for obvious biological reasons experience desire in a much more complex form which cannot be separated from emotional security; for a man sex begins and ends with the act, for a woman it only begins with the act since she has to think of (and normally look forward to) future consequences. Of course, this is not true of all women, and as contraceptive measures become more efficient and women more socially independent, many regard sex in pretty much the same light as men. But women even more than men have been brought up to feel that sex is unpleasant or dirty, and many people of both sexes are afraid to give themselves completely in love (the childhood mechanism: "If I don't give all of myself to others, then they can't hurt me"), so it is hardly surprising that comparatively few lead a completely satisfying sexual life. In any case, mutual adjustment usually takes some time and many men and women may take years to accomplish this. However, with or without complete sexual satisfaction most couples as we have seen lead reasonably happy lives together because their goal is not sex alone but the maintenance of a marriage and a home.

There are some cases in which this is not so and the help of a psychiatrist or Marriage Guidance Counsellor is required: if intercourse is completely impossible, if one of the partners finds it totally repulsive, if the couple desire to have children and fail to do so, or if, as sometimes happens in women, the act by arousing desires which they are ashamed of leads not only to non-completion but to anxiety and emotional tension. When this happens, the wife may find that following intercourse her nervous tension brings about irritability and this in turn may lead to constant bickering that may threaten to wreck the marriage. All these cases require skilled advice though, of course, they are no ground for worry on physical grounds alone nor are they anything to feel ashamed about. Everybody fails from time to time in some aspect of their lives and, if it cannot be dealt with by ordinary means, the sensible thing to do is to seek expert advice; there is no more need to feel embarrassed about seeking help from a psychiatrist in these circumstances than in seeking help from a lawyer or house-surveyor in others.

The Goal of Self-Realisation.

Gordon Allport, a leading American psychologist, has emphasised that every living being is trying to complete his own nature—in the terms already used here, he is striving towards self-realisation. But his search, depending upon parental attitudes, may take one of two roads.

One road seeks safety through exclusion, through a restrictive and rejective equilibrium employing the mechanism of repression and denial, yet, because the more we repress the more we must continue to repress, the personality inevitably becomes impoverished and incapable of free self-expression. The person clings to a narrow island, restricts his circle, sharply selects what reassures him and rejects what seems to threaten him. The other road is one of relaxation, self-trust, and therefore trust of others. "There is no need to exclude strangers from one's gathering. Self-love is compatible with love of others. This tolerant orientation is possible because security has been experienced in the realistic handling of inner conflicts and social transactions. Unlike the authoritarian and prejudiced person, the tolerant person does not perceive the world as a jungle where men are basically evil and dangerous."

Teaching Morals.

The disasters arising from a restrictive upbringing have to do with the child's early failure to live with his own impulses; he is made to feel guilty and punished whenever he soils himself or is found handling his own genitals. (Incidentally, research has demonstrated that mothers of prejudiced children are mostly likely to punish the child for this offence.) He is punished or made to feel guilty too—and only a child can tell what guilt and pain can be aroused by the hurt and suffering expression on a mother's face which is much worse than a physical blow—whenever he has a tantrum or strikes a parent or other relative. A child who finds his every impulse, even his desire to self-expression, wicked, and feels that he is unloved when he gives way to it—is likely to grow up hating himself for his many transgressions. Says Allport: "He carries a burden of infantile guilt. As a consequence, when he sees any lapses from the conventional code in others he grows anxious. He wishes to punish the transgressor, just as he himself was punished. He develops a dread of the very impulses that trouble him. When a person grows overconcerned with sin in others, the tendency may be viewed as a 'reaction formation'. Having had to fight unholy impulses in himself, he cannot be permissive and lenient toward others. (This) moralism is only surface compliance: it does not solve the conflicts within. It is tense, compulsive, projective. True morality is more relaxed, internal, and congruent with the life pattern as a whole."

The Development of Normality and True Morality.

The way to avoid these developments is obvious. In addition to the fundamental parental attitudes already mentioned, the basic rule is *never to apply prohibitions to a child until it is capable of carrying them out and understanding them.* For example, the senseless attempt to 'train' a child in potting habits before the muscle controlling bowel movements has even been developed is something which is carried out to suit the parents' convenience rather than for the child's own benefit as, alas, in many cases are the sleeping habits and regular feeding habits imposed upon the infant. What parents should realise is that to a considerable extent normality and genuine moral attitudes are developed by a process of internal maturation rather than by any sort of direct intervention on the part of the father or mother whose real job in the early years is to provide the right emotional background. The child who is fed 'on demand', that is, whenever it wants, does not become an anarchist but in a few weeks develops as regular a rhythm as the unfortunate who has regular feeding imposed upon it; the child who is left alone so far as bowel-training is concerned learns control by itself in the course of time.

Young children naturally play with their genitals which, after all, are an interesting part of the body and, quite apart from sex, an obvious object for attention: they should be left alone to do so unless the parents prefer that the child should learn to do the same thing in secret or, worse still, that it should learn that sex is dirty and sinful and therefore to be repressed. In fact the young child's genital play is not initially sexual at all but merely natural curiosity, and it is only the guilt-ridden adult who interprets it in this way.

The Good Parent.

A permissive attitude on the part of parents is the only sensible one because it is impossible to destroy a desire but only to drive it undergroun when it will reappear in far less desirable form Aggression, even more than sex, is dangerous if no permitted free expression in the early years; th child with a temper-tantrum should be hugge and reassured because it is frightened by its i ability to control this terrifying emotion. Trai ing, until the child has acquired the ability t understand what he is told, is a matter of livi and leaving well alone. (Obviously, this does n apply to situations where the child is in physic danger of falling or touching dangerous object but even then the minor accident should b minimised as far as possible because the moth who shows her excessive anxiety infects her chi with it and causes it to feel that the world is dangerous place. It is, but one can handle better when unafraid.) Thus the good pare must strike a useful balance between sincere lo and concern for the child and the avoidance inducing too much anxiety by undue fussing abo risks and illness. So far as dangerous situatio are concerned, the sensible thing to do is to remov or guard against any potential source of dang rather than worry the child about it.

Sex Education.

Sex education has often been conceived as process whereby the child—hitherto assumed be totally ignorant of sex—is, at a certain a (usually puberty), taken aside and given a serio talk either by the parent, or (as some seem to su pose) by the biology teacher at school whose du it is naïvely believed to be. This, of course, simply nonsense. Sex education begins at birt by supplying the child's physical needs, its psych logical need for love, and otherwise leaving it alo to explore its body as it pleases. Later, when acquires speech, the child who trusts its paren and has not been made to feel that there is an thing 'bad' about its natural processes, will sta to ask questions. The rules which should b followed by the parents at this stage are clear:

(1) Every question should be answere *honestly* in a way the child at that age ca comprehend;

(2) The answer should be a simple and *bri* reply to what has actually been asked;

(3) Formal sex education, in the sense of more detailed and scientific account, belong only to the later years of childhood when th parents should continue to answer all ques tions honestly and in the greater detail th child now requires, discussing the *social* im plications of sex insofar as they are capabl of doing so;

(4) Sex will finally become something t be taught by the teacher as part of a cours in general biology.

The reasons for this approach are clear: we hav seen that in the early months it is useless—an worse than useless—to apply prohibitions whic the child is unable to understand. When acquires speech and subsequently goes to schoo it will inevitably obtain some sort of sexual in formation anyhow, so the parents' choice is no between some knowledge and none at all but be tween garbled and often nasty information an that which is decent and honest. In fact, th child whose questions have been answered briefl and truthfully becomes *less* interested in sex excep as one feature of life as a whole than the one wh has been told nothing, to whom the secret and fo bidden knowledge becomes both a private obses sion and a status symbol.

Everybody has a particular desire to acquir knowledge which he or she knows to exist, bu which has clearly been withheld because it i supposedly 'naughty' and 'dirty'. Thus se education is a continual process, inseparable fro education in general; it is, in fact, merely on aspect of personal relationships and should b taught as such. What the child should learn i that, since no form of sex is harmful *in itself*, th

ly practical considerations to be taken into count are whether any given sex act is hurtful either person involved, a breach of their self-pect, or a risk to their future happiness—as, for ample, an unwanted pregnancy. It would be ong therefore to encourage someone to engage any sort of behaviour which their religion aches them to be evil, even if we ourselves lieve it to be harmless or even good.

e-marital Relationships.

There are social reasons already mentioned why e-martial relationships *may* be more frequent, d it seems likely that this trend may continue increase. But we might well wonder whether ose who are so alarmed about it (and no decision to its moral desirability can be made here, since is must be left to the reader) are fully aware of background. It is usually assumed that morals e becoming more lax in this respect, whereas a rge part of the truth is that people are simply ore frank and at less pains to conceal what ey do. Again, the kind of behaviour con-mned by the moralists is very far from being w: for instance, in the heyday of the Church aring the Middle Ages what was then more kindly scribed as the 'natural' child was not only as ll treated as the child born in wedlock, but the rm 'bastard' was applied to many exalted ople as an honourable title. In agricultural societies—including our own—when children were garded as an important asset, engaged couples liberately sought pregnancy because the man anted to make sure that the woman was fertile fore marriage. Another obvious reason for the pparent increase in illegitimacy is that the 'shot-n' marriage is less frequent, and a woman who s become pregnant will not marry her lover if e subsequently decides that he is unsuitable; is is surely a tendency in the right direction since good can come of an enforced marriage and, in ew of the stigma still attached to illegitimacy, ows that the young take these matters more riously today.

4. SOCIAL PATHOLOGY.

We are now going to glance very briefly at cer-in aspects of what are regarded as some of the ore important problems of our day and, since is only possible to select a few, those chosen re juvenile delinquency, neurosis and the stress iseases, and what appears to be an increase in oredom and discontent.

hanging Social Attitudes.

Take first of all the background. There is a remendous technical revolution going on in which ere exists a lag between the actual environment which we live and our ability to adjust to it; e real enemy, however, is not so much lack of bility as ignorance and superstition. For ex-mple, it is indeed true that malnutrition is a orld-wide problem, but it is necessary to realise hat the causes of hunger are just as often political nd religious as the result of any lack in foodstuff. n Asia, one of the main drawbacks to an adequate iet is the caste system of India which prevents ertain foods from being eaten and in communities n both Asia and Africa, as people earn more oney, they frequently spend it, not on food, but n clothes and bicycles. Attitudes require hanging at least as much as the agricultural ystem; *for all the attitudes which we regard as pecial problems are common to every country in* ***hich industrialisation and democratisation are*** *aking place* and the mass media are not the cause ut merely a single symptom of this total process. Rebellious youth, for instance, and the search for nore possessions and affluence is as much in vidence in the Communist countries where the nedia have been used not only to indoctrinate but lso to improve, and they are just as common in the ew countries where the mass media hardly exist. n our own country the working class are doing xactly what the middle class were doing when hey first got into power, only more obviously to ecause of the narrowed time-scale within which social change takes place: gambling, buying rather tasteless objects, building rather ghastly houses and fitting them with equally ghastly furniture, reading bad books (the women's maga-zines of today are really no worse than the writings of Ethel M. Dell and Ouida) and horror comics (which were invented in the late eighteenth cen-tury, and the most famous, *Frankenstein*, was written by the wife of Shelley). Of course, the middle class to a considerable extent are still doing these things—but they dislike the working class having the same freedom. Just as one can well imagine the first time that the well-to-do on the Riviera looked with distaste on the newly affluent grocers and 'tradesmen' who were beginning to flood into 'their' preserve, so today the descend-ants of the grocers and tradesmen view with the same distaste each favourite resort as it becomes flooded with newly affluent workers.

The Cost of Affluence.

But affluence is a state for which a price has to be paid, particularly by youth. In modern society teenagers for the first time have money to spare, are socially emancipated, reach puberty earlier, and have far greater possibilities for success (and failure) than their forebears ever had. A society based on the concept of social mobility, whether the goal is wealth, affluence, or status, must necessarily be associated with striving and the more sensitive members will feel more strongly than others the pressure to achieve, to avoid failure, or even to maintain their present position. In addition, if one has been indoctrinated with the belief that success is essential to self-respect and that affluence is 'normal', it is not surprising that the failures will try to walk round the ladder if they are unable to climb it, *i.e.*, they may attempt the devious way of criminality. Whereas in former times people stole because in some sense they were genuinely deprived, today they do so because they feel relatively deprived. Since happiness is not an absolute, the affluent society aided by the power of commercial advertising ensured a state of affairs in which there is always a gulf between what people have and what they think they are entitled to. Crime and neurosis are the two sides of this single penny; for, as Freud pointed out, whilst the criminal is in open rebellion against his society, the neurotic is in a state of unconscious rebellion. Which 'solution' is selected depends upon a number of factors, one of the most im-portant being social class; for the unsatisfactory upbringing that will tend to make the middle-class boy neurotic will tend to make the working-class boy *living in an area where delinquency is a socially-accepted pattern, or at least not a wholly condemned one*, into a delinquent. Here, of course, we are referring, not to the whole working class, but to specifically delinquent areas.

The Delinquent.

Among the most striking facts about crime are (*a*) that it is predominantly a male, adolescent, and working-class activity; (*b*) that it is at its height in the 14–17 age-group; and (*c*) that, not only do crimes become less violent after the age of 30, but they tend to cease altogether in the majority of cases. An obviously important con-clusion of (*c*) is that the majority of delinquents would stop their behaviour regardless of what was done whether by way of punishment or 'treat-ment'.

It is completely fallacious to suppose that a large majority of criminals of all categories are suffering from some form of mental disturbance, and for the sake of convenience it is useful to consider the following categories: mere wildness and 'proving offences', the disturbed and violent delinquent, the sexual offender, and the pro-fessional criminal or old lag. Of course, there are other groups such as those who habitually engage in fraud, blackmail, and shady financial trans-actions, but these can be fitted into the last of the above categories.

The first type of case is very often a perfectly normal boy who is simply engaged in 'working off steam' and doing the sort of things most of the rest of us have done, since aggressiveness and a

certain amount of destructiveness are usual accompaniments of adolescence, or, in the case of the 'proving' offence, he feels the need to demonstrate his toughness or lack of fear by engaging in crimes which are clearly not carried out primarily for personal gain. Typical of these are those who smash street lamps, steal apples or other goods, damage railway property, and so on, or the group of boys who break and enter an office yet, whilst smashing up some of the furniture, steal nothing but a few pencils or other worthless objects. These form the vast majority of all cases and the act, as a German criminologist puts it, is "an episode rather than a symptom", *i.e.*, most of these cases are normal and will develop into perfectly good citizens. More dangerous is the delinquent who takes crime seriously and is often violent towards his victim. Whilst the first group can belong to any class, this group usually comes from a disturbed home and a delinquency area—which is not at all the same thing as saying that he is necessarily abnormal though he may need help: nevertheless, except in grave cases, even this type tends to outgrow his criminal tendencies or, at least, to become less violent after the late twenties. In other instances he may develop into the old lag.

Sexual perversions are, of course, the concern of the psychiatrist and need not be discussed here, but it should be noted that most perverts are suffering from a lack of sexual drive rather than, as popular belief would have it, a state of being 'oversexed'. They are rarely dangerous and most are sexually impotent in normal relationships, but even those who murder with a sexual motive tend to have the same incapacity and a surprising number (*e.g.*, Christie and Haigh) have been brought up in oppressively religious households. The professional criminal is frequently just that, and those who seek complicated psychiatric explanations for his behaviour are usually wasting their time; few people seem to realise that there are those who take to crime as a 'career' just as others become doctors or carpenters. In many instances they are merely 'following the dear old dad'. The old lags or recidivists who form such a large proportion of our prison population are commonly dullards but it is doubtful if many are in the clinical sense mentally ill. As the late Sir Norwood East, one of Britain's leading criminologists, said: "As the result of more than fifty years' practical experience of crime I am unable to regard crime as a disease, although sometimes the result of it."

Crime and Punishment.

Since the great majority of criminals who show early delinquent tendencies simply grow out of them, it is doubtful whether punishment (or for that matter, psychiatric treatment) has any great influence upon the course of events, though detention may often be necessary. But it is really more than doubtful whether punishment has any preventive effect at all. On the contrary, we know that severe corporal punishment can often arouse such a store of resentment as to last through a lifetime of violence and it is also well known that many people commit crimes in order to be found out because they are unconsciously seeking punishment.

How many, one wonders, are aware of the following facts: that the annual average of murders per million of the population in Britain has increased from 3·2 in 1931–40 to 3·3 in 1951–60; that over a fifth of male murderers commit suicide; that between 1955 and 1960 only 31 per cent of offenders were wholly responsible for their actions and that a number of those sentenced to life imprisonment subsequently had to be sent to mental hospitals; that about half the male offenders killed wives, children, or parents, 10 per cent girl friends, and about a quarter strangers (*i.e.* murder is largely a family affair); that, of about 150 murders a year less than a dozen are not cleared up; and that murders with a sexual motive average 8 a year. Murder is therefore very unlike any other form of crime in that its incidence hardly changes from year to year, the number of mentally disturbed cases is large, the vast majority of murders are due to family or intimate quarrels where gain is seldom the motive, and (except for the occasional psychopathic murderer) the crime is unlikely to be committed again.

Stress and Mental Illness.

Before discussing this problem we must say something about the nature of mental illness, and the first point to note is that, apart from the fact that all cases of mental illness show symptoms of disturbance in thought, emotion, or behaviour this is the only factor that they do have in common. Without encroaching too far on the material presented by the writer of the Medical Section, mental disorders can be roughly classified as psychoses (*i.e.*, the insanities), the neuroses which are minor if very uncomfortable conditions differing from the psychoses mainly in that the psychotic patient does not realise that he is ill whereas the neurotic is all too aware of the fact; the psychopathic personalities who are people that are more of a trouble to society than to themselves; the mental defectives suffering from defect of intelligence; and the psychosomatic diseases in which actual physical disease has been brought about by mental stress.

The causes of these conditions are very various some like the so-called organic psychoses being really physical diseases with mental symptoms brought about by infections such as syphilis or toxins such as alcohol, others such as mental defect being either inherited or caused by damage to the child before birth. The functional psychoses, such as schizophrenia or manic-depressive insanity, have no known physical cause though some authorities believe that they have discovered abnormal substances in the body fluids of schizophrenics. But with these exceptions (and possibly a few cases of so-called psychopathic personality), we have to realise that '*mental diseases' are not in any meaningful sense diseases at all but cases of social maladjustments.* From this fact the following important conclusions can be drawn:

(1) that the neuroses and the psychopathic conditions—insofar as the latter term has any meaning at all—are really the result of faulty upbringing resulting in a basic defect in interpersonal relations and the symptoms are usually brought on by a precipitating cause when the individual is confronted by a problem which, by reason of his early experiences, he is unable to face;

(2) that, unlike ordinary diseases, neurosis is not something that one 'has' but something that one 'is';

(3) that, since nobody has had a complete and perfect upbringing, everybody is in some degree neurotic and it is therefore meaningless to suggest that a person is either neurotic or not—what we usually mean is that he (or she) is neurotic to a degree which troubles him (or her) or troubles others.

The latter is the criterion upon which the person is declared to be suffering from a neurosis and since this is obviously a matter of individual judgment, it follows that all statistics purporting to tell us the incidence of neurosis in a given community are to a large extent based on valueless judgments and of very dubious validity.

The figures are made even more absurd by the fact that there must be countless thousands suffering, for example, from a fear of enclosed spaces (claustrophobia) who have never seen a doctor in their lives and simply solve the problem by travelling by bus and avoiding the underground, and even more who are not aware that they are neurotic at all; they may have 'nervous indigestion' for which they medicate themselves with pills, or believe—as plenty of people do—that the state of 'nerves' is a physical one brought on by overwork and curable by a 'nerve tonic' or 'nerve food'. These, too, may never see a doctor because they are perfectly satisfied with their own medicine. Again, perhaps the sort of neurosis that does most harm is the sort of behaviour described earlier when we were discussing harmful influences on children: the possessive and jealous, the mother-in-law who

annot leave well alone, the suspicious wife or usband, those with a profound sense of guilt ith which they may infect others. All these are uffering from behaviour disorders but few indeed ee a psychiatrist.

he Structure of a Neurosis.

We must distinguish between the early roots of eurosis which are laid in childhood, *e.g.*, the unatisfied need for love and security, resentment gainst authority, and other undesirable patterns f behaviour which, being unsatisfied, continue to epeat themselves throughout life, and the nmediate cause of a breakdown which is the esult of the individual's applying these outdated atterns to new situations. The main difference etween the relatively neurotic and the relatively ormal is that the neurotic tries to apply old olutions to new situations whereas the normal erson takes every new situation on its own erits. Thus the man who has had a conflict etween his desire for self-realisation and the uthority of a repressive father does not distinuish between different authorities in later life, ontinues to act on the belief that all authority s bad, and naturally frequently finds himself in rouble. The man or woman who has felt some enial of love in childhood, continues to seek the ymbols of love throughout life in stereotyped ays even if these take many different forms. he individual may become promiscuous, feel ictimised, become parasitic upon others, overeat, r constantly strive for more goods or status. It s not that all these forms of self-expression are ecessarily bad in themselves: what makes them eurotic is that they are compulsive. Broadly peaking, then, there are two main types of onflict, that which shows itself in the search for pproval, love, status, and goods, and the other ype which is a crisis of self-expression, the free-om to assert oneself. The one is shown in the erson who looks for affluence, the other in the person who seeks for power, even if both have a common root, the search for security.

Boredom and Anomie.

Many people are bored today because, instead of seeking contentment within, they are in the position of a spoilt child who has been offered so many things that he does not know what to do with them since none is a substitute for love. Whatever point he reaches, there is always something more to desire and each goal as it is reached is less satisfactory than the last. Not only is success less satisfying than it once appeared, there is also the danger of falling from the position achieved, and those who want what they cannot have may become no less neurotic than those who have got what they wanted and are afraid of losing it. It is not only people who want who develop a neurosis but those who have achieved their dreams: the East End family moved to a new town is often troubled by the idea that they will be unable to keep up with the higher standard set by others—there is a 'success' no less than a 'failure' neurosis.

A feature of modern society was described by the French sociologist Durkheim as *anomie*, the feeling of futility and not-belonging as old groups are broken up and the mass becomes the 'lonely crowd'. Social mobility has introduced the working-class student to new ways of life which often arouse a conflict between his attitudes towards his family and the atmosphere of Oxbridge; the worker's new desire to get on often alienates him from his mates; and the housewife stranded at home knows, unlike her predecessors, what she is missing—life is passing her by. There is a gulf between what we want and can have, between what we are and what we want to be; our society is characterised by a never-ending search for the end of the rainbow and for security that will never be ours. The only solution is to learn to live with conflict by seeing our own personal problems as problems to be shared and understood together.

III. WORK

1. THE SATISFACTIONS OF WORK.

Work, no matter how we define it, is not simply omething that we have to do in order to make oney to do something else; it is the main source n modern society of status—the sign of approval f other people. In the words of an industrial sychologist: "Work is the source of man's most asic satisfactions, it is his social catalyst—the urveyor *par excellence* of his status and prestige among his fellows." In former times, status came rom one's social position, rank, position in the hurch, craftsmanship, or some special ability; ut few of us today are lords, churchmen, or raftsmen and it is our job that tells others what ve are. Even from the psychological point of iew, it is desirable that our aggressive or creative irives should find expression in doing the sort of ork that fulfils and helps towards the goal of elf-realisation. Of course, many people are ctively dissatisfied in their work, many more atisfied, and others feel that, however well they have done, they might have done better. So it is worth discussing, first, what is satisfying about work, and second, the process of education and selection for work.

Work and boredom are not necessarily related, because from the earliest times work has often been objectively boring but subjectively interesting. To the woman washing clothes in the stream, or to the man planting rice-shoots, boredom was unknown because what they were doing made sense to them. The craftsman in medieval times took pride in producing a good and useful article. One unfortunate result of the industrial revolution was that, while in the long run it created more wealth and goods and benefited more people than any comparable period in history, it was at first step for the majority of workers in the direction of taking the meaning out of work. As Christopher Salmon has said: "Because the Victorians regarded work in industry as necessarily hard and disagreeable they made little effort to introduce tolerable conditions into mines and mills, and foundries, and were content to think of industry itself as an economic necessity instead of as an element in society."

For work to be agreeable it should be meaningful, and, since most people are sociable to a greater or less degree, the company of one's workmates is important. These are two of the factors which, apart from material rewards, the manager or the industrial psychologist has to consider, and some of the modern views on the subject of incentives will be mentioned later. It will become evident that conditions have much improved in the course of this century, but there is no doubt that they might be very considerably better. The fact that work is not only necessary to man but necessary to most people's mental health as well as being an activity that it is normal to like, stands out in odd contrast to a background of industrial unrest. We shall have to ask ourselves what it is that transforms a necessary and ordinarily pleasant activity into a source of strife.

2. EDUCATION AND SELECTION.

The Past.

In former times education was a privilege of the few and compulsory education was not introduced into this country until as late as 1870. The sort of training given by well-to-do parents to their boys was based on the classics and its intention was to create the cultured gentleman at ease in company and able to discourse intelligently on as many subjects as possible without appearing to be too uncomfortably intelligent. Since science was not regarded as a very cultural pursuit and, until the seventeenth and eighteenth centuries, chemistry and physics were still 'natural philosophy' and hardly existed as sciences in the modern sense, it was little taught at school. Those who practised it were comfortably-off

gentlemen who, living more or less in isolation, became interested in it as a hobby. It was only the founding of the Royal Society in 1660 that began to bring these people together to exchange ideas and, since the Society was given a Royal Charter by Charles II, science began to be respectable. Its respectability, however, was conditional and the condition was that it should remain theoretical because gentlemen were not expected to work towards practical ends.

From this attitude there arose the unfortunate distinction between pure science and technology which bedevilled British science and caused parents to feel that technical schools and colleges were somehow inferior to the universities and grammar schools. Of course, another unfortunate result has been that, whereas Britain has never been short of ideas, their serious application has often been carried out in other countries: obvious examples are the jet engine and penicillin. Until much more recently girls, apart from a smattering of languages, music, and drawing, were taught almost entirely such crafts as might be expected to make them good housewives, and the daughters of wealthy parents were not even taught the domestic arts—indeed, since it was believed that any sign of intelligence was likely to put off a prospective suitor, many manuals of instruction suggested that they should actively conceal what intelligence they had.

The Modern Educational Outlook.

Much of this has changed with the acceptance, at least in theory, of the equality of the sexes and the realisation that, as a nation, we cannot afford to waste our human resources. Children are carefully selected at an early age in terms of their abilities and the intelligent child, regardless of his origins, has the opportunity to reach a position consonant with his gifts. But, just as the science-technology dichotomy still persists, whatever governments may say, so other traces of past attitudes make freedom of opportunity less real than might at first appear. Women have not yet gained full equality and we have already seen that what they have gained is more by way of an addition to their traditional tasks than a release from them. One of the greatest barriers to social equality is less any sort of physical barrier confronting the working-class child than the traditional attitudes of his class. It is easy to see why history has made solidarity a traditional working-class virtue and why the boy who tries to better himself is often regarded as a traitor to his class, nor is it unnatural that many workers regard education as synonymous with childhood as work is synonymous with manhood. High culture is still regarded with suspicion as the special province of the ruling class in spite of the fact that, at least since Elizabethan times, most of our great writers and artists have been of comparatively humble origin. These intangible attitudes are obviously a serious barrier to working-class children, as are also the difficulty of finding sufficient privacy to study, the pressures of the affluent society which cause them to want as much money as possible as soon as possible, and the not infrequent family problems centering around the cultural gulf between the university-trained youth and his relatively uneducated parents. Lastly, there is the problem peculiar to England where accent (at least in the south-east) is class rather than regional, and, as Bernard Shaw once said, the child cannot open his mouth without revealing his origins. In a country in which social snobbery is still very real, many can forgive a Scottish, Irish, or Welsh accent, but not a Cockney one. Physical barriers exist, too, because the smaller classes, sometimes the better quality of the teaching, and the limited number of university places in some areas favour the public school child and it is well known that certain universities or colleges prefer the products of particular schools.

Early Specialisation.

The whole concept of education has radically changed, mainly in the direction of very early selection in terms of intelligence and learning ability, and the tendency to early specialisation. We have moved far from the education of th cultured gentleman when John Vaizey can writ that "it is worth spending money on educatio because it assists the economy, because it provide a skilled and resilient body of workers at all level who help to keep a highly fluid economy going Children are put into various 'streams' an sent to grammar schools, secondary moder schools, and secondary technical schools. Thoug the original intention was that there should be n question of any of these schools being superior o inferior to the other the fact remains that parent are often very upset when their child fails to obtai a grammar-school place and this puts a great de of tension upon family relationships when bot parents and children become obsessed with scho marks and examinations.

The Need for Generalists as well as Specialists.

The situation has arisen out of our need fo experts and many authorities obviously believ that this is the best way to obtain them. On th other hand, many others are clearly worried abou what is happening, the tensions and disappoin ments and discrimination that it leads to, and a even beginning to doubt whether excessiv specialisation is a good thing. Like Sir Charl Snow, they see our nation as coming to be divide into two cultures—the world of the arts ar humanities and the world of science and techno ogy. We need the specialists but we nee 'generalists' too if only because the really creati ideas—the discoveries rather than the inventio —have been produced by men who had wid ranging minds, and though a study of the humanities does not guarantee that one will be humane is rather terrifying to contemplate men specialisin in germ-warfare or inventing nerve-gases, total lacking in any knowledge of the men and th human and natural beauty of the world they a being employed to destroy.

The 11-Plus.

The doubts of the value of attaching too muc importance to the results of intelligence tests ar early progress at school are bringing about movement in favour of abolishing the 11-plu examination and making more use of the compr hensive school. London, for example, has decide to abolish the 11-plus or any sort of single te which decides whether children should go to gram mar school or not, and this, in part, is due to th great success of the comprehensive school. In th comprehensive schools in the area, the gramma school, secondary modern, and technical strean study under the same roof and since these childre get equal education the need to select at an ear age is disappearing. Outmoded ideas are rapidl being broken down throughout the country.

Selection Procedures.

Some fortunate people are able to select free the sort of work they would like to do—writers an artists, for example—and others simply slide i and out of unskilled jobs, going where the pay best but the prospects less satisfactory. Today however, the vast majority of people, includin those who are going to fail into the above cat gories, have to go through at some time or anothe in their lives various tests to discover their abi ties. The justification for these tests is (*a*) th present need for able people with particular qual fications; (*b*) the need to avoid wastage b attempting to train people who cannot be traine to the necessary level; and (*c*) the obvious fac that it is a good idea to have a square peg in square hole and a worker who is not only suited t his job but satisfied with it.

There are three aspects of personality which ca be tested in this way: general intelligence, speci abilities such as manual dexterity, engineerin ability, speed of reaction, the absence of colou blindness, and so on, and tests of personality itse —that is to say, the individual's attitudes.

Intelligence tests have already been discusse and we have seen that they are by no mean

fallible; perhaps their main value is negative ather than positive in the sense that, whilst a igh IQ does not *guarantee* academic success, we now that anybody with an IQ lower than about 20 is unlikely to get far in a university. Aptitude ests are less likely to be met with by the average itizen, being mainly employed where a specific ob requires specific abilities (i.e., in situations here we know that before the individual is taken nto the job he requires a certain minimum of uality x unless time is to be wasted, efficiency iminished, or danger incurred.) Obviously an ir pilot must be able to react quickly, an engine river capable of distinguishing between green nd red signals, a musician possess a good ear for one, and so on. Most of these tests are very ccurate and nobody who fails them need feel ' let down ' because they are in his or her own nterests as well as those of others.

Personality Tests.

The personality test is a procedure which, when pplied outside its original field of psychiatry, has iven rise to a good deal of controversy. One of ts earliest forms, still used in conjunction with he lie-detector employed in criminology, was the vord-association test devised by Jung at the eginning of the century to discover hidden com- plexes. In this a list of words, some neutral and others which are believed to have special signi- icance for the patient, is slowly read out and the estee is asked to respond as quickly as possible with the first word that comes into his head. His reaction-time is measured with a stop-watch, and any delay or hesitation or any unusual responses noted. These give clues to unconscious problems.

Today, however, the usual form of personality est is what is known as a projection test, now videly employed in industry as well as in psychiatry o discover much more accurately personality raits of which the individual is probably totally unaware himself—indeed, his unconsciousness of he traits is almost a necessity for the use of the est. The three tests of this sort which the reader s most likely to come across are the Rorschach or inkblot test, the Szondi test with its photo- graphs of oddly-assorted individuals, and the TAT or thematic apperception test in which the outlines of vague human figures in various postures in relation to each other are shown. In the first, the estee is asked to say what he imagines himself to ' see ' in the multicoloured inkblot, in the second, he is asked to say which of the people in the photo- graph he would prefer to sit with in a railway carriage and which he would most dislike in these circumstances, and in the third he is asked to write a story about the shadowy figures. As the name indicates, all three tests are based on the same idea—that, presented with a vague situation to which he has no outward clues, the testee will project upon the figures or shapes his own atti- tudes. When a picture of an apple is presented to anyone, he has no choice but to recognise it for what it is, but when he is presented with a Rorschach inkblot what he ' sees ' in it must come from h'mself. In this way, such traits as intro- version or extraversion, authoritarianism or humanitarianism, latent homosexuality, sado- masochistic trends, and the degree of integration or otherwise of the mind can be fairly reliably assessed.

Criticisms of Personality Tests.

These procedures are widely used in the selec- tion of management in America and have been severely criticised. The most cogent of these criticisms are: (*a*) the moral one that it is an invasion of privacy and that no one at a man's place of work has any right to knowledge of the most intimate type about himself which, if he knew, he would not wish to be communicated; (*b*) the factual one that, although the tests are probably scientific, the uses to which they are put in industry are not, since nobody knows what makes a good manager good (in other words, un- like aptitude tests in which one knows what one is looking for, projection tests reveal material which is only of interest to the psychiatrist); (*c*) the fact that, given knowledge of the technique of the tests, it is very easy to cheat at them. (Those who wish to learn how to do so should consult W. H. Whyte's book *The Organisation Man.*) All that is necessary is to imagine that one is moderate in all things, has no unduly strong feelings either for or against parents and relatives, has conservative views on politics and religion, and has been good—but not too good—at all the tasks one has been presented with throughout life. That, to sum up, one is an insufferable prig and a complete bore.

Group Tests.

Another type of test, or rather group of tests, is that carried out in management selection and at officer selection boards for the army. Here a group of about ten applicants are asked to spend a week-end at a country house (in the case of industry); they are given batteries of tests from intelligence tests to TAT personality tests, are in some cases seen by a psychiatrist who has the test results, and are carefully observed as unobtrusive- ly as possible by trained observers as they in- teract with each other. The fundamental part of the programme is the group task in which various assignments are given to the group as a whole and, in the course of time, it will be found that, in the discussions as to how these tasks are to be accom- plished, those who have superior organising abilities and other useful qualities come to be recognised by the group as its informal leader. Thus in this type of test, it is the group itself which chooses (consciously or unconsciously) the most suitable applicant—not, of course, by votes or words but by behaviour. He is the person who is most frequently turned to for advice during the carrying out of the task, which naturally is related to the activities for which the group is being tested. In the case of industry, for example, it will be the solving of an imaginary business problem, in the army it is usually a problem involving doing things of a para-military nature. All that one can say of this method is that it gives the candidate a better opportunity than the individual interview, since he is checked by a fair number of people and this eliminates the prejudices of selection by one person.

3. THE PROBLEM OF LEADERSHIP IN MODERN SOCIETY.

What has been said above leads us directly to the question of leadership, not necessarily in industry, but in modern society as a whole. We have seen that in many cases there still exists the belief that ' leadership ' is a psychological trait which is somehow situated inside a person, being either there or not. Oddly enough, so far as industry and the services are concerned, this innate quality is most frequently found in those who have had a public school education—indeed, one of the mainstays of the argument for retaining public schools is that they train the ' character ' and produce qualities of ' leadership ' denied to lesser breeds. Scientifically speaking, this is the merest nonsense (*a*) because one can no more train character in a public school than in a borstal or any other place—that has, for better or worse, occurred in the home in the early years of life, and (*b*) because there is no such quality as leadership within a particular man or woman, only the ability possessed by nearly everyone to be a leader in a given situation. Many pieces of psychological research have shown that the only common factor found in those who become leaders in a particular field is their superior competence or knowledge in that area. Of course, many people are thrust into positions of leadership by reason of their social position, their wealth, their education (not what they have *done*, but *where* they have *been*), but these are leaders only in the formal sense and, if many products of our public schools have made good army officers, that is first because they have supreme self-confidence and, second, because they were acting within an authoritarian network in which even the less competent had the full backing of authority behind them. Even the self- assurance is more likely to have been derived from the social background of which their school is only one aspect than from any training within the

school itself. This sort of leadership is all very well for the army which of its very nature must be authoritarian, but it is of no use at all in a modern democracy in which a leader must be chosen because he represents the feelings and views of the group he leads. The reason for saying this is not a sentimental one or based on political faith in democracy; it is simply that, in a society which is not authoritarian and where there is more or less full employment, there are no means open to a leader to get his subordinates to work effectively or even to stay with him than by possessing their confidence and respect.

Leadership as a Function of the Working Environment.

We have seen that leadership is a function of the situation confronting the group, so it follows that if the situation changes the leader may have to change too. This is well illustrated in the following case: a factory manager who had been well liked and respected retired and his place was taken by a bumptious, self-assertive man who did not believe in consulting his subordinates. Hitherto, the supervisors had formed their own group which elected one of their members to deal with their interests or problems when he took them to the factory manager for advice, help, or information. Throughout the period of office of the first manager, the supervisors' leader was a quiet, sensible man and the two got on very well together and with the rest of the men. But when it was seen what the new manager was like, resentment began to grow and, at the next election, the old leader was ousted and the man put in his place was an agitator who had up till then been regarded by most of the supervisors as aggressive, unpleasant, and even a little 'cracked'. Year after year the same man continued to be elected in spite of the fact that each member of the group still continued to dislike him, and when they were asked why the answer was: "Well, you see, he's the only man amongst us who is capable of dealing with that (unmentionable) manager."

A Tartar philosopher, more than five hundred years B.C., made the observation that the great ruler is one whose people do not even notice his existence, the lesser one is feared, and the still lesser one despised. This is confirmed by the leading American authority on management, C. I. Barnard, who wrote that the good leader in industry in a democratic society may sometimes give the impression that he is a "rather stupid fellow, a mere channel of communications, and a filcher of ideas. In a measure this is correct. He has to be stupid enough to listen a great deal, he certainly must arbitrate to maintain order, but he has at times to be a mere centre of communication. If he used only his own ideas he would be somewhat like a one-man orchestra, rather than a good conductor, who is a very high type of leader." Or, as the same Chinese philosopher wrote:

> The best employer of men keeps himself below them.
> This is called the virtue of not contending;
> This is called the ability of using men.

In a democracy politics is 'the practice of the possible' because the leader can never be too far ahead of the desires and attitudes of the people.

The Nature of Democratic Society.

A democratic society is, of course, in one of its aspects a society which elects its leaders by secret and universal voting; but this is not the only, or even the most important part of democracy. In modern societies it is often necessary to put people in high positions because of their specialist knowledge—government by amateurs is now no longer possible in all fields, and in industry and other spheres such as the armed forces it is not always possible to elect leaders. What is much more important is (*a*) that the leaders at all levels even when they have been chosen primarily because of their technical qualifications should be able to make themselves acceptable to those under them, and (*b*) that there should be free flow of information both up and down the channels of communication. This is not achieved by manipulating others on the model of Dale Carnegie's book *How to Make Friends and Influence People*—which is often used as a means of influencing people without necessarily making friends of them—but by being the sort of leader described by Barnard who acts, not on his own decisions taken in isolation, but with regard to the feelings of others and an ear to their opinions. There would be far fewer strikes if management employed genuine joint consultation in which no major decisions were taken on matters affecting the workers without consulting them about the decisions beforehand, seeking their cooperation and advice as to how they should be carried out—and this not because of common decency alone but because management *in fact* cannot act without the cooperation of their employees. Indeed, many strikes happen not because the workers object to the decisions as such, but because their human dignity is affronted by not being told about them. Sometimes it is necessary to make decisions, for example, about redundancy, which on the one hand may be inevitable and on the other hardly likely to be pleasant to the workers, but in these cases there is all the more reason why they should be kept informed from the earliest stages and allowed, at least, to express their views as to how the process can be carried out with least hardship.

An Effective Communication System.

One of the secrets of good management is an effective communication system; for workers will do their job efficiently only when they are able to identify themselves with their firm and feel that they are taking part in joint enterprise rather than being used as mere tools. Thus it must be possible for all grievances to be dealt with openly at the earliest moment and everybody in a factory ought to know what he is doing, for whom he is doing it, and why—the days of 'You're not paid to think: do what you're damn well told,' are, or should be, long past. The widest publicity must be given to the firm's finances, its future projects, its exports, and sales within the country because, as we have seen, nobody works satisfactorily unless he can feel that his work is meaningful. The real essence of democracy is not any special technique but the confidence of the ruled that they can influence their rulers, trust them, and receive justice at their hands.

Social Mobility.

Social mobility is another characteristic of a democracy, and we have seen that in England the barriers to the right man finding the right job and attaining the highest status of which he is capable are psychological and based on traditions rather than the result of any legal or physical hindrances. Indeed, it is surprising to note that social mobility in Britain is freer than in the United States in spite of the latter country's tradition of 'from log cabin to White House'. Probably the main reason for this, as Vance Packard has suggested, is that the American manager has little chance of success unless he is a WASP (White, Anglo-Saxon, Protestant) and, of course, industry is the main field controlling social mobility and status. In Britain the main obstacles for a man are the dying 'old boy' tradition and the worker's fear of leaving his class, but for a woman the sole obstacle is simply the fact of being a woman.

4. THE DEVELOPMENT OF INDUSTRIAL PSYCHOLOGY.

We turn now to a brief account of the discoveries in the field of industrial psychology which had its beginnings in the United States at the turn of the century. One of its first exponents was a man known as Frederick Winslow Taylor who was to become famous—and, in the eyes of some, notorious—as the founder of the system described as 'Taylorism'. The principles of this system were simple:

> (1) to select the best man for the job;
>
> (2) to instruct him in the most efficient methods and the most effective movements to employ in his job;

(3) to give incentives in the form of higher wages to the best workers.

By applying these principles—which, in a more mane form, were to develop into modern Time d Motion Study—Taylor was able to reduce the mber of workers needed to load wagons at his m, the Bethlehem Steel Company, from 500 to 0, increase daily earnings of those who remained 60 per cent, and save his bosses about 75,000 llars a year. He was, not unnaturally, unpular with the workers who, to this day, have ways tended to dislike the man with the stopatch and if Taylor as a sincere Quaker was basiily a humane man and hoped that his system uld benefit all, he nevertheless held the very odd ilosophy that "all employees should bear in nd that each shop exists first, last, and all the me, for the purpose of paying dividends to its vners".

About the same time Frank B. Gilbreth was ncouraging the fragmentation of work which, as e have seen, was already an increasing tendency roughout the middle period of the industrial volution in an attempt to increase efficiency and, be fair, decrease the amount of hard work ecessary. Like Taylor, his ideal was to make ork so simple that "it could be carried out by a ained chimpanzee". Neither of these two men as a trained psychologist; they only entered the eld about the time of the First World War and oncerned themselves mainly with experimenting h such environmental factors as the influence of mperature, humidity, noise and so on, on efficicy, but the total effect of all this early work was increase the meaninglessness of the job, arouse sentments in many cases, and cause the workers feel that they were being exploited. Since it is ecessary to most workers to feel that what they e doing is meaningful and worthwhile, it is now nerally admitted that if, from the economic oint of view, many of these researches were really uccessful, the early investigators took a far too mple and mechanistic view of the nature of the roblem. The philosophy lying behind them mplied the beliefs (a) that man was a machine or, any rate, that his mind could be ignored since e real problem lay in adjusting the physical vironment or the way of doing the job; (b) that e only incentives were 'the carrot or the stick' -that is money or the negative incentive of fear losing one's job; (c) that these propositions were lf-evident because only a privileged few ever arn to like their work.

he Hawthorne Researches.

These assumptions were to receive a rude shock ith the so-called researches carried out in the arly 1930s by Elton Mayo and others at the works f the Western Electric Company in the United tates. Mayo was an Australian working at arvard University who initially started off with he same assumptions as his predecessors and ontemporaries—basically, that the main factors n improving output were the conditions in the hysical environment of the work-room and, when Western Electric called on him because they were aving labour problems, he proceeded to put them nto force. In a work-room where a number of irls were assembling telephone relays, Mayo and is colleagues began by altering the lighting in the oom and, after a time, were gratified to find that roductivity went up. Subsequently various ther improvements were made in the way of restreaks, atmospheric conditions, and new wage lans and, following each improvement, the higher utput continued to rise steadily. Whilst carrying out these researches, the group of psychologists had kept on talking to the workers, asking or their views and even for advice, thus arousing real interest in what was going on. However, s a good scientist, Mayo did not merely accept, s others had done before him, the satisfactory esults of his work but decided to put them to more igorous tests. The environmental 'improvements', the breaks, the better wages plans, were removed one by one and, when all had been removed and the girls were working in their room with lighting which was of about the intensity of bright moonlight, it was found that production figures soared far beyond the highest level ever recorded. The conclusions of this piece of work were the now commonplace ones that the rise in productivity and efficiency had nothing whatever to do with environmental changes but were due to social factors such as the girls' attitudes towards each other. Approval, antagonism, or indifference directly affected production, whereas a feeling of importance at being selected for the study, a sense of responsibility and mutual cooperation with the researchers, and growing congeniality among themselves caused a general improvement. In short, it was conclusively proved that human relationships between one worker and another and between all and management motivated them more strongly than financial incentives or good working conditions.

Incentives.

Social surveys carried out by numerous workers in this country and the United States under the influence of Mayo showed that *in all cases money was one of the least powerful incentives*—to take a single example typical of many, the 17,000 employees of Joseph Lucas Ltd. in England put security first and high earnings fourth in a list of seven items which they were asked to place in order of importance. Of course, it has to be remembered that this may change when inflation occurs and prices rise and it may even be the case that, in an affluent society, workers may want more money as an aim in itself, but generally speaking the demand for higher wages is more likely to reflect either dissatisfaction with the firm or a concern with 'differentials'. That is to say, since the workers have their own informal status hierarchy, one group may feel aggrieved if those of a lower status have their wages increased in such a way as to lower the relative prestige of the other—it is the prestige rather than the money that matters, *e.g.*, when the very low wages of the lower grades of railway workers were raised, the engine drivers demanded correspondingly more, not because they begrudged their work-mates their increased affluence, but because their self-esteem had been hurt. The following are some of the relevant facts about incentives in general:

(1) There is no single ideal incentive, because incentives vary greatly from one culture to another (we have seen elsewhere that one of the difficulties in motivating workers in South America and the Afro-Asian countries is their lack of interest in bettering their material conditions), and from one individual to another (*e.g.*, one man may value money whilst another may find more leisure or opportunity for promotion a stronger stimulus to work);

(2) The law of diminishing returns applies to all material incentives, *i.e.*, as the reward increases the desire for further reward decreases until it reaches vanishing-point. Thus the miners, when given higher wages, increased their absenteeism, because the point had been reached at which the need for more money had become secondary to the need for more leisure;

(3) Incentives may conflict with each other: for the worker may ignore financial incentives if he fears that the rate for the job may be cut or that he may work himself out of a job;

(4) It is necessary to realise that in our own culture all motives tend to become 'monetised' since people have subconsciously been taught to believe that money is the key to satisfaction and, when they feel that something is wrong, naturally ask for more money—as Gordon Rattray Taylor has noted "a demand for money undoubtedly indicates that they want *something*, but it does not tell us what".

Restrictive Practices.

We have already seen that incentives can conflict with each other, and one of Mayo's researches demonstrated very clearly the phenomenon of restrictive practices arising from such conflicts. In what was known as the 'bank-wiring room' of

the Western Electric Company, he found a group of male workers who completely disregarded all financial incentives and, though the incentive plan provided that the more work a worker did the more money he received, productivity remained at 6,000 units a day in spite of the fact that without the least difficulty the group could have produced 7,000. Here Mayo found that the informal group, which he believed to be the basic unit in industry (it has been described elsewhere as the 'primary group'), had selected an informal leader who was not the same person as the official one. There was an unofficial code of behaviour which exerted a strong influence over group members and impressed upon them the following rules: "You should not turn out too much work, otherwise you will be a 'chiseller'." "You should not tell a supervisor anything to the detriment of a work-mate, otherwise you will be a 'squealer'." "You should not 'act officious'—if you are an inspector, for example, you should not act like one." These are, of course, as Sargant Florence points out, the same sort of principles as are found in the English public school: "'Rate-busters have been called 'swots', chisellers, 'slackers', squealers, 'sneaks'. Americans apparently had no name for the form of behaviour described as 'acting officious', but familiar English slang is 'swank'." These form the basis for restrictive practices in industry though here the need to maintain status and avoid the traditional fear of insecurity plays a greater part.

Summary of Mayo's Researches.

Mayo's important conclusions can be summarised as follows:

(1) Work is a social activity in the sense that, even when working in physical isolation as in the case of the artist, what is done is carried out either in society or for society.

(2) The social world of the adult is primarily patterned around work activity.

(3) The need for recognition, security, and sense of belonging is more important in determining workers' morale and productivity than the physical conditions under which the work is carried out.

(4) A complaint is not necessarily an objective recital of facts; it is commonly a *symptom* manifesting disturbance of an individual's status position. Contrary to general belief, the majority of strikes are not about wage claims, but about matters in which the workers feel their status or self-respect to be threatened.

(5) The worker is a person whose attitudes and effectiveness are conditioned by social demands from both inside and outside the work plant.

(6) The change from an established to an adaptive society—*i.e.*, one in which there is great social and geographical mobility, and where a traditionally static society has given way to mass democracy—tends continually to disrupt the social organisation of factories and industry generally.

Two of the dangers of high geographical mobility are (*a*) that a constantly mobile population never has the time to develop loyalty to individual members or individual firms—as one supervisor said, his department was more like a procession than a work-room because its members were continually changing; (*b*) since social control by the superego or conscience is less effective in many fields than control by group-membership, those who never stay in a community long enough are apt to become 'rootless' with a subsequent weakening in moral control. This, of course, is one of the reasons why immigrants are peculiarly liable to get into trouble. It is not their innate wickedness, but the fact that they have left the community which originally supported their moral beliefs, their old cultural imperatives have weakened, and they have not become sufficiently identified with their new surroundings to accept the current mores. Hence the social phenomenon of gangsterism during the 1930s in America was almost exclusively an Italian or Irish one—in fact, even now, the old secret society founded in Sicily and known as the Mafia, virtually rules a large sector of modern gangsterism.

(7) Group collaboration does not occur accident; it must be planned for and develope If group collaboration is achieved, a cohesion m result which resists the disrupting effects of t mass society.

CONCLUSIONS.

What we have found in this brief survey is th society is constantly changing in order to ada itself to a new environment which itself alters wi disconcerting and ever-accelerating speed. follows that it is incorrect to say that 'huma nature' is always the same and that mo standards never change—on the contrary, should be evident by now that changes in the fields are not only inevitable but desirable. course, there are a few basic laws which a 'absolute' in the sense that they are firmly bas on the nature of society—*e.g.*, "Love thy neig bour as thyself" is a fundamental rule simp because society, by definition, is a state of affa in which most people are neighbourly, and Stua Chase has said that if more than 10 per cent of a community failed to cooperate, the communi would simply collapse.

'Free competition' may well have been in t interests of society as a whole in a developi economy, but it is neither possible nor desira now—in fact, it was brought to an end some ti ago, not by the machinations of wicked socialis but because capitalists could not keep up with t pace and began to combine to protect their o interests.

Again, though we have not presumed to p scribe in what direction sexual morality shou change, there is not the slightest doubt that it changing and will continue to do so. What have suggested is that sexual relations must based on mutual respect and, when that is do nothing serious is likely to go wrong. This v the fundamental meaning of the teachings Christ when he shifted the emphasis from externally applied laws of the Ten Comma ments to inward intentions and motives. Ho ever, no matter how important sexual moral may be, it is very far from being the whole morality and we might guess that one of reasons for the general decline of interest in churches has been their tendency to equate with sin to the exclusion of the social injusti which people feel to be among the major issues our times. If this does not always apply to individual churchmen, it does in general apply their churches. Very often their influence been on the side of reaction as in Spain, and was an Anglican clergyman who described church as "the Tory party at prayer" but, aga there are many exceptions, such as the attitude the Church of Scotland to African affairs and last Encyclical of Pope John.

In the field of industry what has been said b may be summarised in the words of Goronwy Re "It seems sometimes, today, as if the grand co mittee of management which has for so long c ducted the affairs of the country has at last beco conscious of its failure and seeks desperately fo cure. Hence the 'lofty symbols', the 'admo tions', the 'signals for a change of heart', wh we are offered daily. But how are our manag to cure themselves, and where, in the short t that may be left to us, are they to discover eit the knowledge and competence, or the powers will, energy, and creativeness, which today many of them conspicuously lack?" Much same might be said of some of the workers' lead who cannot divest themselves of wholly outda notions and superstitions.

We have tried to show that there is a more ho ful side to the picture presented, notably in field of education; but what is clear is that rad changes in attitudes are needed on all fro What mainly hinders this is not only the ba ward-looking traditionalist mentality but, od enough, the 'affluent society' which, along w its many benefits, has brought about the state affairs described by J. K. Galbraith, the emin economist, and lately American Ambassador India, when he pointed out that "in a coun where well-being is general, the astute politic will be the one who stalwartly promises to def the *status quo*."

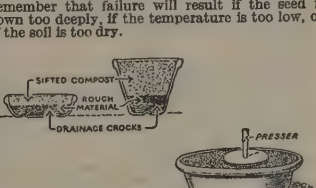
MODERN GARDENING

CULTIVATION OF FLOWERS.

Throughout this section the notes must be
en to refer to cultural conditions in the British
s, although in many cases the information can
adopted to suit the necessity of readers living
road. Undoubtedly, in many temperate parts
the world interest in gardening has increased
rmously during the past decade or so, despite
fact that numbers of large gardens have ceased
exist and that few people can afford to pay for
l-time help in their gardens. To counteract
s, the all important labour-saving garden has
ne into its own; shrubby plants have replaced
nual bedding schemes and large lawns put
wn instead of herbaceous borders or beds of
rticular plants.
n addition, the owner-gardener is anxious to
ll himself of the excellent selection of modern
ls; thus the conventional hoe is being replaced
the "Swoe" or the Wolf pattern of Dutch
eder, both of which are very easy to use, and
ging can be done quickly—and with much less
rt—by using a German digger called a "Ter-
" spade. For grass mowing, the work is
ily done with motor mowers like any of the new
ttery-driven patterns.
For greenhouse work, smaller houses are being
ed and one, say, 12 ft. by 8 ft., can be run
nomically with a minimum winter temperature
40° Fahrenheit by the introduction of trouble-
e, thermostatic heaters or the turbo-heaters,
the moment, besides automatic heating, the
ototypes for automatic ventilation and watering
making an appearance.
While advocating the use of such appliances, it
st be pointed out that there are also to be
nd tools, sundries, and fertilisers of little value,
d many of which have never been properly
ted prior to being put on the market. It is,
erefore, a good plan to discuss the comparative
erits of any appliance or horticultural sundry
th a competent horticulturist or to contact a
blic authority. In particular, many local horti-
ltural societies have special trading facilities,
d the merits of most garden things are generally
own and discussed among members.
Throughout this Guide the vexed question
change in scientific name has been dealt with
liberally as possible and, whenever necessary,
nonyms and cross references are given. In
aling with cultivar names, that is, varietal
mes like rose 'Peace,' reference is made
recommended in *The International Code of Nomenclature for Cultivated Plants* (1961). By so
ing, the references are right up to date and
rther information on any particular plant or
bject is easy to find. For the purpose, a few
andard works of reference are given after each
ction. Normally, all the plants mentioned in
e text are available through the usual trade
annels.
After each plant listed there is a note on its
opagation. Generally, this is the easiest or
ost efficient way of doing so, but it is not
ecessarily the only means. Details of the various
ethods employed are as follows:

Seed. Generally speaking, the early spring is
e most suitable time for sowing seeds of trees
nd shrubs besides those of herbaceous plants and
pines. Where only a few plants are needed, the
ed can be sown in pots and a suitable compost
ade up with 2 parts of soil, 1 part of peat, and
part of coarse sand. Before sowing, the pot
ould be stood up to its rim in water so that the
oil is soaked. Then the seed can be sown thinly
nd covered with a light sprinkling of sifted
ompost.
For very fine seed, like begonias or azaleas,
e seed must have only the merest "sugaring"
f sand just sufficient to anchor it. When
own, the pots should be covered with a pane
of glass (to prevent evaporation) and kept, if possible, in a warm greenhouse or frame. With this method of propagation it is important to remember that failure will result if the seed is sown too deeply, if the temperature is too low, or if the soil is too dry.



CORRECT PREPARATION OF SEED POTS AND PANS—Note provision for ample drainage and compost to rim of its container. After sowing, the containers are covered with a sheet of glass.

Cuttings. There are two main types of cutting: soft-wood cuttings made from fresh, green shoots in the spring and summer and hard-wood cuttings made of mature or semi-mature woody shoots in the autumn. A soft cutting is taken about 3 in. long, the lower leaves removed and a clean cut made through a node in the stem. These are then inserted in pots containing a light, sandy soil or a rooting medium such as horticultural vermiculite, well watered, and covered with a bell jar or plastic bag. Delphiniums, hydrangeas, and lupins are all propagated in this way.
Hard-wood cuttings are taken in the autumn and made from shoots about 8–12 in. long. These are inserted in a sandy soil out of doors or in a cold frame, and left to develop for a year. Blackcurrants, forsythia, and roses can be propagated by this means.

Layering. This is one of the easiest ways of propagating the majority of woody plants, and is used to increase stocks of plants like clematis, lilacs, and rhododendrons. Normally, layering is done in the autumn or spring when suitable branches are pegged down. On each of these the young shoots are, in turn, pegged down and tips turned upwards and tied in position. To encourage rooting, gritty sand and peat should be worked around each layer, and usually the young plant can be severed from the parent after about eighteen months.

Division. By this method it is easy to propagate the majority of herbaceous plants, some rock-garden plants, and a few shrubs. A few herbaceous plants, like delphinium and paeony, are slow to get established after moving, and here the method should not be employed. In any case, old plants should not be split up in a wholesale manner; instead, it is far better to select a few young healthy plants, divide these, and replant the best of the young shoots, in the autumn.

ALPHABETICAL LIST OF ORNAMENTAL PLANTS.

Abutilon.—The greenhouse species is often used in public parks for bedding schemes. *A. vitifolium*, with white, mauve, or blue flowers makes a fine wall shrub for warm gardens. If given full sun it will quickly reach 10–15 ft., but is sometimes short-lived. *Prop.*—Easily raised from seed sown in March in a warm greenhouse or frame.

Acer (Maple).—Hardy, ornamental trees; the Norway maple is often planted for its magnificent autumn colour and as a lawn tree. *A. palmatum* and vars. constitute the Japanese maples; all colour brilliantly in the autumn but do not grow freely unless given some shade and a light soil rich in humus. *Prop.*—Seed, layering, or budding.

Achillea (Yarrow).—Grey-leaved perennials for open border or, dwarf species, for rock garden. Valued as a cut flower, particularly *A. ptarmica* 'Perry's White,' with double, white flowers and *A. eupatorium* 'Gold Plate,' with large, flat, yellow flower heads. *A. millefolium* is a pernicious weed of turf (T34). *Prop.*—Division in autumn.

Acidanthera.—Scented, bulbous plant introduced from Abyssinia. It is not difficult to grow if the corms are planted in the spring and lifted in the autumn for storing in a frost-proof shed. It requires a sunny position and plenty of water in the summer. *Prop.*—Offsets removed when the old crop of bulbs is lifted.

Aconitum (Monkshood).—Blue-flowered perennial plants particularly useful for lightly shaded positions or full sun; flowers from May to July, height 3–5 ft.; roots poisonous. *Prop.*—Seed or division.

Adiantum.—*See* Ferns.

A Well-Grown Agapanthus—In winter the pot should be kept in a cold greenhouse or some protected place; in summer afforded full

Agapanthus.—A bulbous plant, native of South Africa, usually found in seaside gardens and sometimes grown in tubs; flowers blue, violet, or white. It needs winter protection in the form of a covering of bracken or straw and a light soil heavily enriched with manure. Worthy of wider cultivation. *Prop.*—Seed or division in March.

Ageratum.—Blue-flowered carpeting plant. *See* Annuals.

Allium (Flowering Onion).—A genus of nearly 300 species of bulbous plants widely distributed over the Northern Hemisphere. The foliage has the distinctive smell of garlic, but some species are grown for garden ornamentation; in particular *A. roseum*, valuable late-flowering rock plant for dry positions. *Prop.*—Offsets, taken from parent bulbs in the spring.

Alstroemeria aurantiaca (Peruvian Lily).—This tuberous-rooted, herbaceous plant is often grown for cutting. Flowers orange-red and height 2–3 ft.; of easy culture if afforded a sunny position and left undisturbed. For best results apply liquid manure or soot water when growth starts. *Prop.*—Seed or division.

Althaea (Hollyhock).—A truly delightful, old-world plant, but not often seen, as modern hybrids have given way to rust disease. Best grown in rich, heavy loam. Mulch with manure of a sort and stake as necessary. *Prop.*—Seed June, thin out, and transfer to flowering positi in September. Although a perennial, in so localities the best results are obtained by treati it as a biennial and raising a small supply a nually.

Alyssum.—Low-growing annuals and perenni for rock garden and sunny border. The pere nial, *A. saxatile*, is deservedly popular by reas of its bright, spring flowers and value as a w plant. The variety 'Citrinum' is bright yell and 'Dudley Neville' biscuit-yellow. *Prop.* Perennial sorts by cuttings in June.

Amaryllis belladonna.—Often this plant is co fused with the greenhouse, bulbous plant, *H peastrum*. The true amaryllis is a half-har bulb for planting at the foot of a warm wall; has white to pinkish-red flowers. When plantin cover neck of bulb with an inch of soil and lea undisturbed, as the plant resents moving and slow to get established. Lack of flowering generally due to planting too deep. Establish clumps may be fed with hoof and horn meal 2 oz. per sq. yd. in July. *Prop.*—Divide a replant clumps in early July.

Amelanchier canadensis.—A large shrub small tree; valuable for its spring flowers a autumn colour. As it will grow almost anywhe in sun or shade, it makes a good plant for inform screening. *Prop.*—Seed or layers.

Amepelopsis.—*See* Parthenocissus.

Anchusa italica.—A blue-flowered perenn with fleshy roots, growing to a height of abo 3 ft. Responds to feeding and needs a positi in full sun. *Prop.*—Root cuttings in the sprin division in the autumn.

Anemone.—The tuberous-rooted section cludes the 'Caen' and 'St. Brigid' strai These are best grown in an open position in lig rich soil; plant in October, lift and store wh foliage dies. The hardy, fibrous-rooted per nials are varieties of *A. hybrida* (syn. *japoni* and constitute one of the most accommodating perennials, being particularly useful for dar shady positions. Worthy of wider attention fr gardeners. *Prop.*—Perennial sorts by division autumn.

Annuals.—These are plants which develop fr seed, flower, fruit, and die within a year. Ad tionally, some perennials, like antirrhinums, m be treated as annuals for the convenience of th cultivation. Sunny borders may be plant solely with annuals, they may be interplant with perennials, used for window boxes, or, oc sionally, in the rock garden. All sorts do best well-worked, light loam enriched each year w a dressing of fish meal at 3 oz. per sq. yd., t days before sowing or planting.

In the division of the group Hardy Annu may be sown in the open ground as soon as co ditions permit during March or April where t plants are to flower. Wet or cold soils will g many failures, and fine seed should be cover only with the lightest sugaring of soil. Oft surprising—but delightful—results may be o tained by sowing broadcast mixed seed of annu specially offered by some trade houses.

To raise Half Hardy Annuals, seed may sown in early March in a warm greenhouse and t seedlings pricked out into boxes. Subsequent the plants are grown on in a cold frame, gradua hardened off, and then transferred to their flow ing positions towards the end of May.

Anthemis tinctoria.—Hardy perennial w feathery, grey foliage and flowers in varying sha of yellow. Height 2–3 ft., needs full sun a good for cutting. *Prop.*—Division in the autun *Anthemis nobilis* is the chamomile sometim unwisely used to make lawns.

Antirrhinum (Snapdragon).—The popular be ding plant requiring a good soil and position full sun now largely in disfavour owing to r

ase; planting should be restricted to rust-stant varieties. *See* Annuals.

phelandra squarrosa.—An evergreen, perennial t introduced from Brazil. Often sold as a se plant, albeit a warm temperature and a humidity are necessary for its cultivation. en grown indoors it is best discarded when the ers fade and the foliage starts to wither, as it not be successfully grown on from year to under normal conditions indoors.

quilegia.—The modern race of hybrids are the lt of much interbreeding with wild forms to a wide range of colours. Best when planted light shade where soil is naturally moist. p.—Seed in late spring; transplant to flower-position for following year.

rabis caucasica.—Once known as *A. albida*, common rock plant is often used on dry walls. double-flowered form is particularly good. p.—Cuttings in July; a fresh stock should be ed regularly, as the special forms tend to die

raucaria (Monkey Puzzle).—This tree was in-uced from Chile, where it forms large natural sts, and widely planted in Victorian days. wning of foliage suggests lack of water in the mer or, occasionally, effects of very cold ther. It should be planted in a position ected from the prevailing wind. *Prop.*—Seed warm greenhouse.

rmeria maritima.—A hardy perennial with or red flowers in the spring; must be grown ll sun where the soil is dry. *Prop.*—Division flowering.

rtemisia.—A genus of shrubs and perennials able for sunny borders or rockeries. *A. lacti-* is among the best of the herbaceous species, ng grey foliage and creamy-white flowers. *A. anum* (lad's love) in the shrubby section has fragrant foliage. *Prop.*—Herbaceous sorts by division; shrubs by cuttings in the early mer.

rundinaria.—*See* Bamboo.

ter (Michaelmas Daisy).—By careful breeding plant has been improved out of all recognition. many first-class varieties are available in the e. Responsive to good cultivation, it is used ts colour late in season and properties as a flower, particularly *A. yunnanensis* 'Nape-' and *A.* 'Barr's Pink' A wide range of urs are available besides some fine, low-grow-forms. In the border one pleasing combina-can be made with *A.* 'Harrington's Pink' *Scabious* 'Dinkie.' *Prop.*—The clumps should plit up *annually* in the spring, and only the pest pieces of outer root replanted.

ter, China or Common.—*See* Callistephus.

ttlbe.—Allied to the *Spiraea* and useful for ting in moist, rich soils; flowers white, pink, crimson; height 2 ft. *Prop.*—Division of ps.

ubrieta.—A name often misspelt. Through-the country it is used as edging or for dry . Many lovely sorts available apart from the monly found, pale-blue variety. It is a lime . *Prop.*—After flowering the plants should everely trimmed and, as necessary, stock eased by division.

ucuba japonica.—Much maligned and over-ed shrub, but one tolerant of neglect and es or smoky conditions. Interesting variants e type, like 'Crotonifolia,' may be found in e lists. *Prop.*—Cuttings rooted in the open dy.

uricula.—Correctly known botanically as *ula auricula*. Flowers of alpine auricu as white or yellow, while in those of florist' ulas are to be found some of the most delicate rings among hardy plants Choice varieties rown in pots under glass; others in moist, shady borders. *Prop.*—Seed or division in the spring.

Azalea.—*See* Rhododendron.

Bamboo.—The common name for the large group of woody grasses, reference to which is difficult owing to the confusion in their nomenclature. Often grown for screening and wind breaks, and is a favourite shelter for small birds; the best for home-grown canes are *Phyllostachys viridi-glaucescens* and *Sinarundinaria nitida*. An interesting account of bamboo growing is found in the *Jour. Roy. Hort. Soc.* (June 1957). Growth can be encouraged by feeding with sulphate of ammonia and mulching with leaf-mould in the spring. *Prop.*—Division of clumps in late spring; transplants must be kept watered until established.

Begonia.—A genus showing wide diversity of form and much horticultural value. Of particular interest is the tuberous-rooted section, of which many of the loveliest varieties have originated in the nurseries of Messrs. Blackmore and Landon at Bath. For bedding schemes, the tubers are started in boxes of rich soil under glass in late March and planted out 9 in. apart in June. During the summer feed with liquid manure of any sort and keep moist in dry periods. *Prop.*—Cuttings in early spring in a warm case.

Berberis.—An extensive genus of beautiful and easily grown shrubs, evergreen and deciduous; the former used mainly for beauty of flower, and the latter for autumn colouring and ornamental fruits. *B. stenophylla* makes a fine evergreen hedge; invaluable for preventing illicit entry by dogs and, even, unruly children. *B. aggregata* and *B. jamesiana* are among the best berrying kinds. Prune in the winter by removing old wood. *Prop.*—Seed in spring or layering in autumn.

Buddleia.—Deciduous shrubs of easy culture for sunny positions. Varieties of *B. davidii* available in a range of colours from purple to white; best when pruned hard by cutting all previous year's growth back to main stems in February. The weeping species, *B. alternifolia*, often grown as a standard; good specimens at R.H.S. Gardens, Wisley. This sort must be pruned in the summer by cutting off the dead flowering stems. *Prop.*—Cuttings in July–August in cold frame.

Cactus.—In the main grown in cool greenhouses or as house plants and, if cultivated well, many will flower every year. As a general guide, plants should be watered fairly freely in the summer and little in the winter, but there are exceptions. A detailed account of growing these fascinating plants will be found in *The Cactus Grower's Guide*, by Vera Higgings (Latimer House), 1946.

Calceolaria.—Seed of the greenhouse biennials sown in June or July for flowering in the following year. Mixed seed provides a wide range of colour. *C. integrifolia* is a half-hardy perennial, raised by cuttings or seed, for greenhouse or bedding work.

Calendula (Marigold).—This common hardy annual is freely raised from seed sown in August. Of easy culture in any sort of soil, although it is worth getting seed of new varieties now available. *See* Annuals.

Callistephus.—The China asters are among the best half-hardy annuals for garden and indoor decoration, but good soil and full sun are necessary for best results. *See* Annuals.

Camellia japonica.—Hardy, evergreen shrub rightly beloved by connoisseurs and cultivated in gardens for many centuries. May be grown in cold greenhouses, woodland gardens, and against north- and west-facing walls; under all conditions camellias must have a moist, acid soil. Best varieties for outdoors are 'Althaeaflora' (dark red), 'Donckelarii' (red, white marbling), and 'C. M. Wilson' (pink). Of recent introduction is the desirable *C. williamsii* bred from *C. japonica* in part; often the subject of television and gardening notes. The dropping of buds is thought due to dryness at the roots at some time

or sharp fluctuation in temperature. *Prop.*— Named varieties by cuttings under glass in early July. Otherwise plants easily raised from seeds if sown in the autumn immediately they are ripe, in acidic peat and kept moist.

Campsis grandiflora.—Sometimes found listed as *Bignonia* or *Tecoma*; choice deciduous climber for warm wall, large reddish-orange flowers in autumn. To encourage flowering growth, prune hard back to old growth in spring. *Prop.*— Cuttings in April struck in a warm case.

Canary Creeper.—*See* Tropaeolum.

Candytuft.—Hardy annual (*q.v.*) and perennials with white, crimson, blue, or purple flowers. The perennial—*Iberis sempervirens*—is a fine plant for a rock wall. *Prop.*—Seed or, perennials, from cuttings.

Carnation.—*See* Dianthus.

Centaurea (Cornflower).—The perennial species are valuable for cutting and border use, and may be found in such colours as pink, crimson, and yellow. *Prop.*—Lift and divide every third or fourth year. The hardy annual, *C. cyanus*, is often sold as a cut flower. *See* Annuals.

Chaenomeles speciosa.—This is the correct botanical name for japonica. The species commonly grown is a wide-spreading, rounded shrub, 6–10 ft. in height, and often used against walls. It is a plant of easy culture with best results being achieved by the annual spurring back of the current season's growth in the same way as an apple tree is pruned. All japonicas can be used for making jelly but, for this purpose, the best one is *Chaenomeles cathayensis*, a gaunt shrub about 10 ft. in height which bears fruit up to 8 oz. in weight. To obtain a crop within a reasonable time, two or three plants may be set in a group about 5 ft. apart. If growth or flowering is below par all japonicas should be fed with "Growmore" and mulched with compost.

Cheiranthus cheiri (Wallflower).—Among the finest displays of this biennial are those found each year in the public gardens of Southend-on-Sea, where it is used in conjunction with bulbs and forget-me-nots. *Prop.*—Seed sown thinly in rows in May and seedlings thinned or lined out and then transplanted in late autumn. The so-called Siberian wallflower, *Erysimun asperum*, which has bright orange flowers, is grown in the same way, but it is intolerant of wet soils. Both sorts are lime lovers, and on acid soils plants may receive treatment with 1 oz. of lime in a gallon of water.

Chimonanthus (Winter Sweet).—Hardy, winter-flowering shrub with heavily scented flowers. Although brought to this country from the Far East in the mid-eighteenth century its garden value is not widely appreciated. The large-flowered, yellow sort, *C. praecox*, is particularly fine, but like all the varieties, it is best grown against a sunny wall and where the soil tends to be poor. If growth is excessive and flowering poor, trim back young growth severely in March to encourage short, spur-like shoots. *Prop.*—Easily raised from seed or layers.

Christmas Rose.—*See* Helleborus.

Chrysanthemum.—Hardy annual sorts are available in a wide range of colours and give a fine display in the summer months. *See* Annuals. There are also a number of perennials such as the shafta daisy and the oxeye daisy for sunny, herbaceous borders; all do well in ordinary soil, but should be lifted and split up about every three years. The plant sold by florists in the autumn is the Japanese chrysanthemum. Many are hardy out-of-doors, but no plant is more responsive to good cultivation and normally is best left to the specialist grower. For ordinary garden work, the best sorts are the Korean and Otley types. Under a brief reference the interesting details of cultivation cannot be dealt with fairly, and reference to specialist books is recommended.

Clematis.—A hardy climber for walls, screes pergolas, and the like. Best kinds are to be fou among named varieties in nurserymen's lists. light, well-drained soil is necessary and if annually with a bucketful of manure or comp the plant will thrive for many years. Occasi ally plants will be found on north walls, and grown in full sun some light protection from sun is desirable for the roots. Varieties wh flower on the *current* season's growth, like *jackmanii*, should be pruned in late February within a foot of the ground; other sorts sho have sufficient old growth removed, after flow ing, to keep them within bounds.

Unfortunately, the climber is sometimes kil by clematis wilt, a disease about which very li is known, and the premature death of young pla should not be blamed automatically on the s plier. *Prop.*—Layering, by which means shoot will often give three or four plants.

Convallaria majalis (Lily of the Valley).—W known perennial that will thrive in any dar shady position. For best results lift every f or five years and mulch annually with old manu *Prop.*—Division when foliage fades.

Coreopsis.—The hardy annuals are found catalogues under "Callipsis," and all will thr in ordinary soil. The flowers are mainly bri yellow, and many are good for cutting. Annuals. Similarly, the perennials have the sa predominant colour and are useful because of t long flowering season and abundance of flow *Prop.*—Division.

Cornflower.—*See* Centaurea.

Cosmos.—Tall-growing, half-hardy annuals t are best grown in full sun in a dryish border. large, daisy-like flowers can be had in a variety colours, including white, yellow, pink, and cr son. *See* Annuals.

Cotoneaster.—Hardy evergreen and deciduo shrubs or small trees bearing scarlet or sometim yellow berries in the autumn. All may be gro in ordinary or poor soil and planted in open shady shrubberies and trailing species used agai walls, over banks, or as ground cover. For shr berries *C. lacteus* and *C.* 'Cornubia' with berries and *C. rothchildianus* with yellow ber are among the best sorts; *C. conspicuus* 'Deco is a strong grower for banks, while *C. horizonta* is an excellent cover for any wall. Planting m be done in the autumn or spring, and no prun apart from occasional shaping, is requir *Prop.*—Seeds and layering.

Crataegus (Hawthorn).—There are many g varieties of our British hawthorn, *C. oxyacant* worthy of attention, particularly 'Coccine (crimson) and 'Paulli' (double, red). All do well on poor soils, and no pruning is requir The common hawthorn makes a stout, impe rable hedge planted 9 in. apart in a double r 9 in. asunder. *Prop.*—Common sort by se choice varieties by budding.

Crocus.—A hardy bulb of great beauty wh was studied for many years by one of the great horticulturists of the twentieth century, the l E. A. Bowles. Does best in rich soil planted bold groups around margins of beds or borc and naturalised in grass. When required, feed early spring with bone meal at 2 oz. per sq. *C. sieberi* and *C. tomasinianus* very early flowerl large-flowered, garden forms about three we later. *C. sonatus* flowers in the autumn and often naturalised in grass. *Prop.*—Clumps m be lifted and divided about every five years, July. The so-called autumn crocus is *Colchic autumnale*. This bears large, lustrous leaves the summer, followed by mauve or white flower of fleeting duration—in the autumn.

Crown Imperial.—*See* Fritillaria.

Cyclamen.—*See* House plants.

Cytisus (Broom).—Only does really well in d poor soils in full sun; choice, procumbent so like *C. kewensis*, used in rock gardens and tall o

open shrubberies. Pruning is important; ots should be shortened after flowering, but old d must never be cut. *Prop.*—Seed and cut- s in August in a sandy soil.

affodil.—*See* Narcissus.

ahlia.—The cultivation of this plant is a cial study, and there are probably more garden eties of it than any other plant. Ordinary enriched with manure and an open position equired. Tubers may be planted 3 in. deep in il or young plants in late May. During the mer feed with soot water and liquid manure. r the first frosts lift, dry, and then store tubers eat or straw in frost-proof place. Many stocks dahlia are affected by virus (T30), and pur- sers should be careful to check source of supply.

aphne.—Shrubby plants, giving some of the t richly scented of all flowers. In particular, e is *D. mezereum*, which requires a damp soil; ire with the shrub is due usually to root dis- ance or virus disease (T31) *D. odora* is one the evergreen, fragrant species. Some re- nces have suggested that this lovely shrub is hardy, but there is no evidence to support the position. *Prop.*—Seed or layering.

elphinium.—Hardy annuals and perennials. latter sorts have gained popularity enor- sly since the War, due in the main to the vities of the Delphinium Society but also to introduction of many very fine new varieties. erican hybrids, like the 'Pacific Strain,' are large but tend to die out and, consequently, the true, perennial habit of European sorts, it some of these have been weakened by the oduction of poor lines. It is important there- to select stocks of strong constitution. phiniums need a deep, rich soil and a sunny tion protected from wind. Plant in autumn apart, feed in the summer with liquid soot er, and mulch with decayed compost or manure e spring. When growth starts, thin out weak ths to leave not more than five stems per t. In winter take steps against possible slug age (T29), and on this point it is beneficial protect crowns with a covering of ashes. p.—Cuttings in the spring or seed; division of ps is a poor alternative.

he hardy annual sorts are the well-known spurs, which grow to a height of 18 in. to 2 ft. may be found in a range of colours including , red, white, and shades of blue. *See* Annuals.

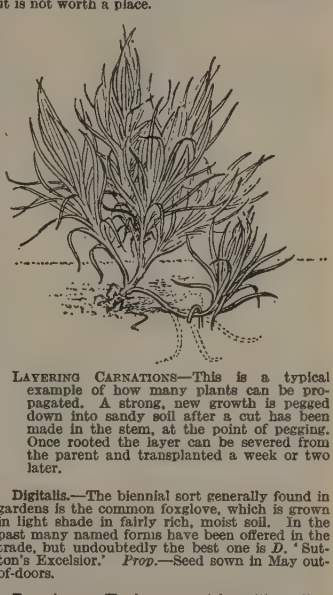
eutzia.—Hardy deciduous shrubs thriving in soil and valuable for their summer flowers of e or whitish-pink shade. To keep the plants rous, shoots should be shortened after flower- and old or weak wood cut out. *D. scabra* is obust habit, reaching about 7 ft., and *D. ntissima* 'Fasciculata' proves a graceful shrub e 5 ft. tall with clusters of about twenty ers coloured rosy-pink and each nearly an across. *Prop.*—Cuttings made from firm ng growths about 10 in. long in sandy soil of-doors.

ianthus.—This name covers a wide range of ual, biennial, and perennial plants. At one e often grown for their fragrance, but to a e extent this has been lost with the introduc- of wider ranges of colour. Border carnations picotees grown out-of-doors need a limy, y rich soil in full sun. Plant in the autumn pring and, as the buds appear, feed with soot er or liquid animal manure, if necessary. se groups are *not* of good perennial habit and uld be propagated annually to ensure con- ation of stock.

he common pink requires the same soil con- ons, and should be propagated when the stock weak; good scented varieties should be ht, and include the 'Imperial Pinks,' 'Mrs. kins,' and 'White Ladies.' *Prop.*—The best hod is by layering in July so that the new ts can be put in their flowering position by September. The lower leaves are pulled off cted shoots and a slit passing through a joint ade in the stem. Each layer is then pegged n with a hair-pin, the pin being placed abov cut. The layers are then covered with an inch andy compost and well watered.

II (77th Ed.)

In this genus is the sweet william; although truly a perennial, it is generally grown as a biennial and, consequently, the plant is raised from seed in May out-of-doors. In gardens where it is prone to rust disease control is most difficult and it is not worth a place.



LAYERING CARNATIONS—This is a typical example of how many plants can be propagated. A strong, new growth is pegged down into sandy soil after a cut has been made in the stem, at the point of pegging. Once rooted the layer can be severed from the parent and transplanted a week or two later.

Digitalis.—The biennial sort generally found in gardens is the common foxglove, which is grown in light shade in fairly rich, moist soil. In the past many named forms have been offered in the trade, but undoubtedly the best one is *D.* 'Sutton's Excelsior.' *Prop.*—Seed sown in May out-of-doors.

Doronicum.—Hardy perennials with yellow flowers; warrants wider planting, as they are among the earliest perennials to bloom and will thrive in poor soil or in some shade. The best is *D. austriacum* flowering in March, height 9 in. *Prop.*—Division after flowering.

Echinops.—Name appropriately derived from *echinos*, a hedgehog, in reference to the spiny, long scales of the flowers. The plant does well in an open position, where the globular heads of steely-blue flowers can be seen to advantage. *Prop.*—Division in March, but best left undisturbed as long as possible, as it must be moved with care.

Elaeagnus.—Hardy deciduous and evergreen shrubs generally grown in rather dry positions as foliage plants. Of the evergreen sort, *E. pungens* 'Aureo-Variegata' has bright golden variegation, and is therefore valuable for indoor decoration during the winter. *Prop.*—Layering in late summer.

Erica.—The heathers are native plants to Britain, and many variants found in the wild have been introduced into gardens to good purpose. Indeed, heathers have become so popular that special Heather Gardens have been made, and two fine examples may be found in the Royal Gardens, Windsor where the planting is new and the Royal Horticultural Society's Gardens, Wisley. Here, different sorts reaching the dimensions of small trees, dwarf kinds, and many scores of interesting variants, to supply flower throughout the year, will be found.

The Scottish heather is, botanically, *Calluna vulgaris*, and, like all British heathers, it is intolerant of lime or chalk. Where alkaline conditions exist, planters can try *E. carnea*—a winter-flowering heather—or *E. darleyensis*, but the results are usually disappointing. When planting all heathers, clumps must be well firmed and after-

wards kept moist; subsequently, mulch all types annually with peat. *Prop.*—Division and layering.

Erigeron.—Hardy perennial for sunny borders; daisy-like flowers freely develop and are good for cutting. *Prop.*—Division in the autumn.

Escallonia.—Slightly tender evergreen and deciduous shrubs. In the Midlands protection of a south wall is necessary; suitable for open shrubbery in the South. Ideal for maritime conditions, and here may be used to good effect as hedges. Many of the best varieties originated in the nursery of Messrs. the Slieve Donard Co. in County Down. *Prop.*—Cuttings under a glass jar in summer; layers in September.

Eschscholzia californica.—A hardy annual of easy culture; height 18 in., flowers mainly shades of orange. *See* Annuals.

Everlasting Flowers.—*See* Helichrysum.

Ferns.—A large number of plants are included under this name and, as they grow wild in many parts of the world, some need hothouse conditions. They are distinguished from flowering plants by their method of reproduction; instead of producing seeds, ferns develop spores, usually on the back of their leaves. The hardy kinds may be grown in equal parts of leaf-mould and soil, and the fronds of leaf-losing kinds should not be removed until the spring, as they offer some protection from the cold. Tender ferns should be repotted when new growth starts in the spring in a compost of equal parts soil, leaf-mould, and sand, using a pot just large enough for the purpose. During the growing season, in particular, keep the roots moist and plants free from a dry or smokey atmosphere. *Prop.*—Division of clumps when growth starts in the spring.

Forget-me-nots.—*See* Myosotis.

Forsythia.—Commonly found in many gardens, as it is of easy culture in any soil. Flowers bright yellow in early spring. To keep in good shape prune directly after flowering by cutting out old wood. *F. intermedia* 'Lynwood' is upright in growth and *F. suspensa* of weeping habit; both types make good wall plants for North aspects. *Prop.*—Cuttings in the autumn.

Foxglove.—*See* Digitalis.

Freesia.—Greenhouse bulbous plant and, if grown for scent, care must be taken to select fragrant varieties. Pot in the autumn in a fairly rich compost and keep as cold as possible until growth is seen. Then bring into a frost-free greenhouse and water freely. When flower stems appear, feed with liquid manure; after flowering, gradually dry-off until time for repotting. Failures almost invariably traced to premature forcing before root growth has been made or growing in excessively high temperature. *Prop.*—Offsets at potting time.

Fritillaria.—The one mainly used in gardens is *F. imperialis*, a handsome, spring-flowering bulb. To grow it *really* well, this species must be given a deep, rich soil and, contrary to some views, it is best lifted every year as soon as the foliage fades. If growth is poor or plants do not flower, feed when growth starts in the following spring with equal parts of bone meal and superphosphate at 3 oz. per sq. yd. *Prop.*—Offsets removed from parent bulb at lifting time. The old bulb should then be replanted at once and any offsets lined out in a nursery row.

Fuchsia.—Greenhouse and tender flowering shrubs. The outdoor sorts (of which *F. riccartonii* is the best) may be grown in light soil in full sun. In the spring prune all growth down to ground level; protect, if necessary, in winter with covering of cut bracken or dry straw. Greenhouse varieties are potted firmly before growth starts in the spring and, when buds burst, all the previous year's growth can be cut back hard. To encourage flowering, feed with a liquid manure, such as dried blood, and syringe foliage in hot weather. During the winter keep plants dry and house in a cool greenhouse. *Prop.*—Cuttings of new gro taken about 1 in. long and inserted in sand u a bell jar.

Gaillardia.—Hardy annuals and perennial in. to 3 ft. high which bear large, richly colou flowers invaluable for cutting in mid- and l summer. Unfortunately, on heavy soil the pe nials are liable to die after flowering, and eve well-drained soils they cannot be considered l lived plants. *Prop.*—Normally it is necessar raise a fresh stock in alternate years; see sown in May in a cold frame and the young pl lined out in a reserve border prior to plantin the autumn.

Galanthus (Snowdrop).—Hardy bulbs worth growing if given a moist, shady posi where stock can be left undisturbed. Plan should be done in fairly bold clumps; bulbs not expensive, and many variants, like dou flowered and tall-stemmed ones, are well wor trial. *Prop.*—Lift and divide clumps in Aug

Gentiana.—The gentians comprise some of most fascinating of all rock-garden plants pa perhaps, because some are difficult to man In particular, *G. acaulis*—which has true "gen blue" flowers—is exacting in its requireme and in many gardens flowering can never induced. What controls flowering has not b discovered, and the plant can be grown we acid or limy soils. On the other hand, *G. ornata* must have an acid soil and is best position out of the direct sun. Beginners v the genus are advised to start with easily gr sorts, like *G. lagodechina* and *G. septem Prop.*—Seed sown in cold frame in March division in early spring.

Geranium.—The true geranium or cranesbi a hardy floriferous perennial for rock garde open border. In the latter case *G. ibericum* (flowers) and *G. sanguineum* 'Lancastrie (rosy-pink flowers) are exceptionally good, both do well in dry, sunny positions. The called "bedding" or "greenhouse" geraniu a pelargonium (*q.v.*). *Prop.*—Seed in March.

Gladiolus.—Dutch hybridists have done m work on this bulbous plant, and many new lovely varieties are now available. The pla responsive to good cultivation, and corms ma planted 4 in. deep and 6 in. apart during the sp in well-prepared ground. When the blooms remove the dead spikes of flower and lift the co in September. After a month—and this poi important—pull off the old shrivelled corm clean the new one. By doing this there is likelihood of spores of diseases overwintering the new stock. Finally, the corms should stored in a dry, frost-free shed, and if given pr attention can be kept for a number of y *Prop.*—Bulbils, removed when the corms cleaned, can be sown in the spring in nursery and will flower within two years.

Godetia.—Hardy annual of easy culture tolerant of poor soil conditions and even s shade. There are many varieties, mainly bright flowers of rosy-pink and crimson. Annuals.

Guernsey Lily.—*See* Nerine.

Gypsophila.—The favourite sort is *G. paniculata* which is often grown for cutting, together wit double-flowered form, 'Bristol Fairy.' To well gypsophila must be given a dryish soil w the roots can penetrate undisturbed; if grow poor mulch in the spring with animal man *Prop.*—Generally done by seed in spring; sp forms by grafting.

Hamamelis.—A lovely, but little grown, wi flowering, heavily-scented shrub. The deli lemon-coloured flowers appear interminably December to February. Although it flower its young stage, hamamelis is slow to get es lished and must be left free of root disturba The best sort is *H. mollis* introduced from Chi 1879. *Prop.*—Usually by grafting; can layered.

eather.—*See* Erica.

dera.—Although ivy is seldom planted nowa-, there are a few evergreens to equal it for ring buildings. The large-leaved ivy with n variegation, *H. colchica* 'Dentato-Varie-' is invaluable for cold or shady walls. —Cuttings in August in shady border out-ors.

elianthus.—The perennial sunflowers are tall, w-flowered plants of vigorous habit. They d quickly and become a nuisance, and there-clumps should be lifted and single, rooted s replanted every other year. The annual ower may reach a height of 10 ft. or so; sced wn out-of-doors in April or seedlings raised r glass in the spring. When the flower bud ars, feed with soot water. The seed may be as food for large birds like parrots.

elichrysum.—Although this is a large group of s, the most interesting is the half-hardy al, *H. bracteatum*, the everlasting flower. n the flowers are fully developed they are ith long stems and hung up to dry for winter ration. *See* Annuals.

eliotropium peruvianum (Cherry Pie).— ted, shrubby plants used for greenhouse de-ion or summer bedding. *H.* 'Sir Edward ' is among the scented varieties and *H.* ncess Marina' is the best dark-purple ty. For really good results, heliotropes need n soil and plenty of water in summer. *Prop.*— ings 2–3 in. long in early autumn or spring, k in sandy loam in a warm greenhouse.

elleborus.—The Christmas rose, *H. niger*, ld be planted out of the direct sun in a moist which has been liberally enriched with leaf-d and old manure and here left free from root rbance. Its large, white flowers appear ularly from December to February with early ring encouraged by protection with cloches. Lenten rose, *H. orientalis*, flowers from Feb-y to April, and it is well worth searching erymens' lists for varieties with a wide range olours. *Prop.*—Division of clumps in the g, with each piece having four or five growth ; the clumps should not be split into small m.

emerocallis.—Hardy perennial for moist bor-either open or slightly shaded. Mulch estab-d clumps in the spring with compost or ure. Many new varieties are coming on the ket as a result of introductions from America, e the plant is popular. *Prop.*—Division.

ibiscus.—The evergreen, shrubby sorts with exotic flowers are widely grown in the tropics can be seen under glass in botanic gardens in ain. *H. syriacus* is a deciduous, hardy spe-little pruning is required, and in full sun it reach 8–10 ft. Normally, it is a free-flowering t of great beauty and, in cases where the rs fail to develop, the stock is best replaced good varieties, like 'Coeleste' (single, blue) 'Woodbridge' (single, red). *Prop.*—Cut-under glass; grafting.

olly.—*See* Ilex.

ollyhock.—*See* Althaea.

oneysuckle.—*See* Lonicera.

ouse Leek.—*See* Sempervivum.

yacinth.—Bulbs generally used for bowl re; often results are disappointing, but onsibility does not necessarily rest with the eryman, as poor cultivation is the most prob-cause. Plant in September–early October later) in peat, loam, and sand, and keep as as possible until growth starts, when bowls be brought into a warm room. Care must ken with watering, as the bulbs must not dry nor the compost allowed to become wet and y. After flowering, plant out-of-doors and nnually in June for replanting in the autumn; bowls a fresh stock is required every year. Failures are mostly due to late planting or faulty watering.

Hydrangea.—A favourite shrub introduced from the Far East. Of the many forms, the one offered by florists, *H. macrophylla*, is the most popular. This can be bought in a wide range of shades, from white and pink through to crimson and blue. The colour will depend on soil reaction; in alkaline or neutral soils *only* white and pink shades can be grown, and blue flowers will be found *only* on acid soil. The intensity of colour can be improved by adding lime in the first instance and flowers of sulphur in the second, but it is not possible to make an alkaline garden soil acid in reaction. Lack of flower is generally the result of buds being killed by cold weather. For this reason, hydrangeas are best not pruned until the late spring; then old flower-heads and any weak or unwanted growth can be cut out. During the summer the plants must not suffer from lack of water.

Among the many other sorts are *H. paniculata*, with large cone-shaped panicles of flower and *H. petiolaris*. The latter plant is a vigorous climber, well suited to cover cold walls or for climbing over dead trees. *Prop.*—Cuttings in July–August in a cold frame.

Iberis (Candytuft).—The hardy annual sorts will thrive in any soil, and may be had in a range of colours. *See* Annuals. The perennial candytuft (*I. sempervirens*) is a good plant for a rock wall and has white flowers in early spring. *Prop.*—Seeds in spring and cuttings in summer.

Ilex.—The ornamental value of our native holly is rarely fully appreciated, bearing in mind that, on good varieties, the berries sometimes persist until March. The greenish flowers are sometimes bisexual, and sometimes male and female flowers are on *separate* plants. For this reason hollies should be planted in groups, and at least one plant of good berrying habit, like *I. aquifolium* 'Pyramidalis,' grown. Some varieties have yellow berries and gold or silver variegations on their leaves. *Prop.*—Seed; special forms by budding.

Iris.—This plant is divided into two main sections: those types which grow from bulbs and those which grow from fleshy rhizomes, with many subdivisions in each of them. Of the latter type, there are the commonly grown bearded flag irises, which, owing to their ease of cultivation and wide range of colours, are appropriately known as the poor man's orchid. Notwithstanding, these irises respond to good treatment, doing best in well-dug soil to which a little manure has been added and a dressing of rough chalk forked into the surface. The site should be in full sun for preference and one that never lies wet in winter. Planting or division of established clumps is done in July, setting the rhizome on the surface of the soil but firming the roots well. To maintain growth and flower, feed annually in the spring with equal parts of superphosphate and bone meal at 3–4 oz. per sq. yd. Iris gardens are not often seen nowadays, but the fine example still maintained at Kew is well worth close inspection.

In the bulbous section the Siberian iris is a graceful plant with delicate foliage, though much smaller-flowered than the flags. They make a fine waterside planting or may be grown in the herbaceous border. The Japanese iris is another water lover, and this has delicate-coloured, clematis-like flowers. On the other hand, for dry, poor, stony soils in full sun the lovely, winter-flowering, Algerian iris, *I. unguicularis* (*stylosa*), is an ideal plant, flowering as it does in December and January. This is a plant which must be left undisturbed after planting in June and if leafy growth is excessive the foliage can be cut back by half in August. Spanish, Dutch, and English types of bulbous iris are often used as cut flowers. These may be planted in ordinary garden soil in the autumn and left undisturbed until signs of deterioration are found.

Japonica.—Common misnomer of *Chaenomeles*. (*q.v.*).

Jasminum.—The yellow-flowered, sweetly scented winter jasmine blooms intermittently

from November to February. It grows in any soil, and is best trained up a wall or grown on a trellis. Pruning consists of cutting out the flowering shoots as soon as the blossoms fade. The summer jasmine is a vigorous climbing plant with white, scented flowers. It needs a sunny position and should be well thinned after flowering. *Prop.*—Layering in summer.

Kalmia.—Hardy American shrubs with clusters of waxy, rose or pink blossoms in early summer. Although slow to get established and requiring a damp, acid soil, the plant is well worth growing. It constitutes a feature of the gardens of the National Trust at Sheffield Park, Sussex. *Prop.*—Seed or layering.

Kerria japonica.—A hardy shrub which will thrive in any garden but is best fed with manure to encourage strong growth. When the yellow flowers fade, the stock should be kept vigorous by cutting out old or weak growth. The plant is named after William Kerr, a young man despatched from Kew to collect plants in China. *Prop.*—Division in autumn.

Kniphofia (Red-hot Poker).—Although these plants are so commonly seen, their full value as late-flowering subjects is not often fully explored. There are a number of good varieties worth growing, such as 'Maid of Orleans' (white, 4 ft.), 'Mount Etna' (scarlet, 5 ft.), and 'Royal Standard' (gold and scarlet, 4 ft.). Of equal value is the dwarf variety with grass-like foliage, *K. nelsonii*. *Prop.*—Division in March; easily raised from seed if so desired.

Laburnum.—Handsome trees with long racemes of yellow flowers the seeds of which are very poisonous. It is not advisable to remove branches, as wounds do not heal well or quickly, and once a specimen shows signs of deterioration it is best replaced with little delay. *Prop.*—Seed or grafting.

Larkspur.—*See* Delphinium.

Lathyrus (Sweet Pea).—For general garden decoration, seed may be sown in pots in a warm greenhouse in early February prior to transplanting out-of-doors in April. When heat is not available sowing can be done in the open in October, setting the seed 4–6 in. apart and 2 in. deep where the plants are to grow. In this case the rows are best protected by cloches. As the plants flower with great freedom and make strong growth, a rich, deep soil is required. During the summer water should be given freely and liquid animal manure or soot water applied weekly when flowering starts. When raised for exhibition, special cultural treatment is necessary. The cause of the condition referred to as bud drop is not known, but it is thought to be connected with low temperature and faulty root action.

There is also the hardy, perennial sweet pea, an old-world plant usually seen at its best in cottage gardens. This plant requires the same cultural conditions, except that the old stems are cut down in the autumn. Three or four different species are available, and all are easily raised from seed sown in the spring.

Lavandula.—The lavender is one of the best known of garden plants. It thrives in full sun in a light soil; old flower heads should be clipped off in the summer, but any cutting back into old growth must be left until the spring. The best garden form is *L. spica* 'Nana Atropurpurea'; it has a neat, dwarf habit, with deep purple flowers, and is available from leading nurserymen. *Prop.*—Cuttings out-of-doors in August–September.

Leucojum.—The spring snowflake flowers in February and is a charming plant for any damp, shady border. Although it has a large flower, it has never become as popular as the snowdrop, despite its ease of culture. It should be grown by everyone who values early spring flowers. *Prop.*—Lift clumps and replant after removing offsets in August.

Lilac.—*See* Syringa.

Lilium.—The lilies constitute a large gen plants, some of easy culture, some demanding most exacting of conditions. For a soil conta chalk two of the best lilies are *L. candidum* Madonna lily, and *L. regale*. The former feature of many gardens in South Wales, w bulbs are planted near the surface of the soil the clumps eventually left to develop undistu Only the easiest-grown lilies are suitable fo herbaceous border and, here, apart from Madonna lily, the tiger and martagon lilies sh be first choices for beginners in the cultivati this genus. *Prop.*—Those referred to above all be raised from seed sown out-of-doors (deep boxes in a cold frame) in the spring. I following April line out into nursery rows pri transplanting to flowering positions. Also pagated by offsets and bulbils.

Lily of the Valley.—*See* Convallaria.

Lobelia.—The bedding lobelias are pere plants best raised as annuals (*q.v.*). They do in a light soil, but should be firmed at plan time to prevent plants dying off during a spell. The handsome, tall-growing lobelias scarlet flowers, like *L. fulgens* 'Huntsman,' be used in herbaceous borders with great e but the roots must be lifted and overwinter a cold frame. These sorts grow to a heig 2–3 ft. and will do well only on a wet, he manured soil.

Lonicera.—The honeysuckles make effe climbing plants if grown on the shady si arches or tree stumps or against north or walls. Care should be taken to train y growth before it becomes hard. Old shoots be cut out each spring to keep the plant w bounds, although space must be available fo development. If growth and flowering is mulch the roots in the spring with old ma *Prop.*—Easily done by layering in late summ

Lupins.—There are two sorts of lupins, p nial and annual. The herbaceous perennial among the most colourful of plants as a res the famous 'Russell' strain being introd Of late years, however, the constitution o plant has been weakened through, perhaps, b ing and virus diseases, and it should be take granted that most stocks have to be replaced two years or even annually in some cases. plant requires a rich soil and is best in ground of lime. Conversely, in poor soil the tree thrives and will reach a height of 7–9 ft.; in full sun and lightly prune into shape flowering. *Prop.*—Both sorts are best r from seed sown in May out-of-doors and t ferred to flowering positions in October. annual lupin may be obtained in a ran colours, and should be grown in full sun. **Annuals.**

Magnolia.—Rightly said to be one of the beautiful of all flowering plants. Contra popular belief, some kinds are of easy cul flowering when young and suitable for gardens. Of course, careful selection is nece and for a specimen on a lawn *M.* 'Soulange (large, white or white, purple-stained flowe ideal. *M. stellata* freely flowers in the y stage, and may be planted in an ordinary b if the soil is lime free. To encourage gro mulch annually with peat or leaf mould, but dig near the roots. The evergreen magno often seen as a fine wall plant in old gar This is the only species which may be pruned long shoots can be cut back hard in April. are a number of non-flowering strains of evergreen one, and unsatisfactory plants are destroyed, as flowering cannot be induced buying a replacement care is necessary in ord avoid *another* dud. *Prop.*—Seed sown as so it is ripe in October; layering.

Mahonia.—Hardy evergreen shrub. *M. folium* is useful as ground cover, and will thri any soil and in any cold, shady position prov the soil is not waterlogged. *M. japonica* has racemes of lemon-scented flowers in the wi inferior sorts are often offered by nurser

r this name. *Prop.*—Seed, suckers, and s.

rigold.—*See* Calandula.

thiola.—The night-scented stock is a hardy al with insignificant purplish flowers which at dusk; grown primarily for its perfume. ersely, the so-called Ten-Week stocks and a tion of these, the East Lothian stocks, have le range of colours. If sown in March they be used for summer bedding or if sown in st overwintered in a sunny frame and grown biennial.

ompton stocks flower earlier than the other , and are grown as a biennial by sowing seed ne or early July and, after pricking out into s, are overwintered in a sunny frame. In districts, if the soil is well drained, stocks may as by careful selection of varieties a long season of flower can be obtained when they are grown in formal borders or naturalised. Thus, a season may be extended with 'Peeping Tom' and 'Covent Garden' (early) and 'Geranium' and 'Buttermilk' (late). The bulbs can be left undisturbed until flowering is affected by over-crowding; the clumps should then be lifted and be divided in the late summer. To maintain vigour, feed annually in February with 2 parts bone meal, 1 part hoof and horn meal, and 1 part sulphate of potash at 2 oz. per sq. yd. The chief troubles with narcissi are due to eelworm (T29) and the narcissus bulb fly (T28). For indoor work, plant in bowls in October and keep in cold place until growth is an inch high; failure is invariably due to premature forcing or faulty watering.

Nasturtium.—*See* **Tropaeolum.**

ER LILIES IN TUBS—Drawing (A) shows a cross-section with correct percentage of water and oil together with water lilies and fish. Drawing (B) illustrates marginal planting with primulas, Japanese irises, and a dwarf coniferous tree.

anted out-of-doors in the autumn, but a e should be kept for filling up gaps in the r.

conopsis.—This genus includes the famous e poppy," introduced from the Himalayas. not a plant of easy culture, albeit large s are grown in many woodland gardens 'sol' conditions permit. After flowering lants generally die, although an occasional may persist. *Prop.*—Seed sown in March.

haelmas Daisy.—*See* **Aster.**

ntbretia.—This bulbous plant is of easy cul- and has a long season of flowering. Many arieties with large flowers are now available, rowth can be kept vigorous by lifting and ng the clumps every three or four years, in early spring 4 in. deep and 6 in. apart and d gardens protect clumps in winter with a ng of ashes.

osotis.—The forget-me-not is grown as a al by sowing seed in May and planting out autumn in conjunction with spring-flower- lbs and wallflowers. Poor varieties freely ish themselves, and these should be de- d before planting any of the really good offered by seedsmen.

cissus.—This botanical name includes plants only known as "daffodil" and "narcissus." ach often grown, the wide garden value of spring-flowering bulbs is not fully realised.

Nepeta (Catmint).—In recent years this edging plant with silvery foliage and mauve flowers has become increasingly popular. When flowering in mid-summer there is no finer display of colour. It grows freely on any light, well-drained soil in full sun. The best sort is *N. faassenii*. *Prop.*—Division of clumps in March.

Nerine.—Lately this lovely bulbous plant has increased in popularity mainly through the varieties introduced from the late Lionel de Rothschild's garden at Exbury. The hardy sort *N. bowdenii* flowers in the autumn and should be planted at the foot of a warm wall in August or September and left undisturbed for many years. As the bulbs gradually multiply and work to the surface, a light dressing of sandy compost, to which has been added a little bone meal, can be applied. *Prop.*—Separation of bulbs in August.

Nicotiana (Tobacco Plant).—This half-hardy annual is grown mainly for its heavily scented flowers, which open in the evening. It is worth remembering that the white-flowered sorts are the best in this respect; scarlets and pinks are very much inferior. *See* **Annuals.** The tobacco of commerce is a different plant, namely, *N. tabacum*.

Nymphaea.—No branch of gardening is more fascinating than the water garden, and for it the chief plant must be the water lily. Basically, the main reason for failure is in the fact that in most pools the *average* depth of water is less than 18 in.; this means that the water is liable to be adversely

affected by extremes of temperature. All nymphaeas should be grown in full sun and where the water is still; in streams it is necessary to utilise a little backwater out of the current. Water lilies are planted in May in large wicker baskets with a compost of three-quarters of loam and a quarter of peat; alternatively, planting sites can be built up with bricks to the desired height. If growth is poor, mould Clay's Fertiliser into the size of pigeons' eggs and drop one around each clump. To maintain a healthy condition in the water, fish should be introduced as soon as the plants are established. *Prop.*—Division of tuberous roots in late May.

Orchids.—In the main, this large group of plants needs greenhouse conditions and specialised knowledge. Their cultivation has attracted the attention of some of the greatest of horticulturists, and detailed references may be found in books like *Orchids, their Description and Cultivation*, by C. H Curtis (Putnam), 1950.

Paeonia.—There are two sorts of paeony, the tree paeony and the herbaceous paeony. The former needs a sheltered, warm position and takes about three years to flower from planting time. The latter sort needs a moist, rich soil, and should be mulched annually in the spring with well-rotted manure; some are known not to flower, and as such plants cannot be induced to do so they should be destroyed. The old-fashioned variety of paeony has been superseded by many fine new varieties found listed by specialists. *Prop.*—Tree paeonies by layering or seed sown in the autumn; herbaceous sorts by seed or division.

Pansy.—*See* **Viola.**

Papaver (Poppy).—The oriental poppy is a hardy herbaceous perennial with striking flowers, intolerant of shade and root disturbance. As it blooms early, it should be set near the back of a border, as the large leaves look untidy later in the year. Apart from the commonly grown, red-flowered sort there are others in shades of crimson, pink, and lavender. *Prop.*—A wide range of colours can be obtained by sowing mixed seeds in May. This is a better method than division. The Shirley poppy is a hardy annual (*q.v.*), while *P. nudicale* is a biennial needing a warm, sheltered position.

Parthenocissus (Virginia Creeper).—This climber, with its brilliantly-coloured leaves, makes a fine sight in the autumn, and there is no better plant for covering brickwork or unsightly buildings with a south or west aspect. It has been suggested (mainly by builders) that the plant will damage stonework or cause dampness. There is little evidence to support these suppositions, and reasons for damage can usually be traced—often without difficulty—to other sources. The plant has had a number of names—*Ampelopsis veitchii* is one—but up-to-date nurserymen are listing it correctly as *P. tricuspidata*. *Prop.*—Cuttings out-of-doors in the late summer; layering.

Passiflora caerulea (Passion Flower).—A south wall in favoured gardens is needed to grow this plant. It is of vigorous habit and, once the framework of branches has been produced, it should be pruned annually in the early spring, by cutting back all the previous season's growth to 2–3 in. of the main stem. *Prop.*—Layering.

Pelargonium (Geranium).—So-called "bedding geraniums," such as 'Paul Crampel,' are really zonal pelargoniums. To maintain a stock, take cuttings in early August and insert in sandy soil around the edge of a pot and overwinter in a frost-free greenhouse. In the spring pot-up singly and use for bedding. Otherwise pot-on after two months and, if early buds are nipped off, plants can be adopted for late flowering indoors. Pelargoniums are easy to grow, but for best results a position in full sun is necessary, and cuttings should be rooted *before* the autumn so that overwintering constitutes no great difficulty.

Petunia.—Although really perennials, these plants, native of South America, are treated as annuals (*q.v.*). They are sun lovers and do best on light soils. Petunias make fine plant sunny window boxes, and particularly happy binations can be made by planting tog varieties such as 'Violacea' (deep violet) 'Cheerful' (pale pink) or 'Flaming Ve (crimson) and 'Cream Star' (pale cream). violet-flowered sorts are faintly scented.

Philadelphus (Mock Orange).—Although fine varieties of this shrub are available f trade, it is not grown as widely as its mer serves. As a scented shrub it has few eq while it is tolerant of poor soil conditions shade. Particularly good sorts worth sear for are 'Albatre' (double), 'Beauclerk' (si and 'Sybille,' which, at 3 ft., is about hal height of the others. After flowering, p annually by removing as much old flowering as possible. *Prop.*—Hard-wood cuttings o doors in November.

Phlox.—A wide range of varieties of the h phlox are offered to make an impressive di late in the season. If grown on light soils shade is desirable, as phloxes do well where the soil is damp. For this reason, mulching a be done annually in the spring with com or animal manure. Failures are usually to eelworm (T30). *Prop.*—Seeds in aut division.

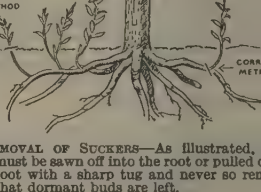
Poppy.—*See* **Papaver.**

Polyanthus.—*See* **Primula.**

Polygonum.—In the main these plants weeds of gardens, although originally they Introduced from the Orient for ornamental poses at a time when their invasive habits not fully appreciated. The one woody climb the genus, *P. baldschuanicum*, makes an adm cover where a very vigorous plant is wa Rampant and unwanted species may be eradi by hormone treatment (T34).

Primula.—Polyanthuses, primroses, green primulas, and the hardy primulas all belong t genus. The first two are the most popular; will do well only in damp soil and respo generous manurial treatment; both are ava in a wide range of colours. *Prop.*—The l more and Langdon strains of seed will g magnificent display of mixed colours. Se warm greenhouse in early March or cold fra April; prick out into boxes and transfer to fl ing positions in the autumn.

Prunus.—A large genus which include flowering peaches, Japanese cherries, and flow almonds. All of them are best left to de



REMOVAL OF SUCKERS—As illustrated, must be sawn off into the root or pulled o root with a sharp tug and never so rem that dormant buds are left.

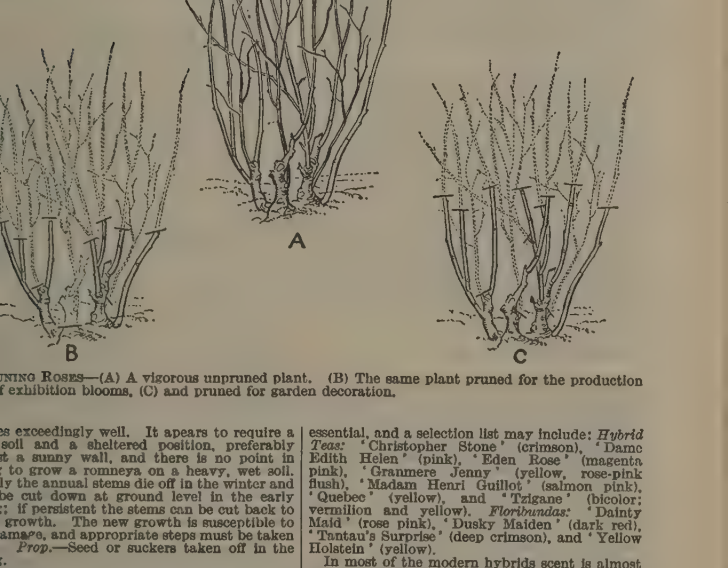
naturally and are not responsive to pruni cutting back in any way. A few sorts are planted in gardens and as street trees (by Superintendents), but anybody wishing to little out of the ordinary would do well to s wide range of some of these lovely trees flow in April and May in our botanic gardens and of the large gardens now under the jurisd of the National Trust. The selection offer nurserymen is often strictly along conven lines. Lack of flower in some seasons can oft traced to bird damage.

Red-hot Poker.—*See* **Kniphofia.**

odendron.—Greenhouse and hardy, ever- and deciduous shrubs, including *Azalea*, something like ten thousand different sorts, impossible to deal with individual require- . General cultivation; an acidic soil is ial, with adequate moisture in summer. If h is poor on established plants, mulch liber- ith animal manure. Beginners should plant the accepted list of hardy garden hybrids. the turn of the century widely planted and xamples are to be found, for instance, in gardens of the National Trust. *Prop.*— and layering.

nneya.—Since its introduction from Cali- in about 1850 the plant has proved a fascina- o gardeners, as sometimes it fails completely lished, spray with "Captan." For a manurial programme, an application of 2 parts of superphosphate and 1 part of sulphate of potash can be applied at 3 oz. per sq. yd. after pruning. Following this, a surface mulch of animal manure, compost, peat, or leaf-mould or a mixture of all of them is given about 2–3 in. thick. Subsequently, if growth is poor, a dressing of nitro-chalk can be made at 1 oz. per sq. yd. Some other manurial treatments, like the so-called "Foliar Feeding" and use of "special" (and often expensive) compounds, have little to commend them.

Where soil conditions are poor and disease prevalent, it is important to buy plants only from nurserymen who take special precautions to ensure that their customers have disease-free stock. Likewise, varieties of robust constitution are



NING ROSES—(A) A vigorous unpruned plant. (B) The same plant pruned for the production f exhibition blooms, (C) and pruned for garden decoration.

es exceedingly well. It apears to require a soil and a sheltered position, preferably t a sunny wall, and there is no point in to grow a romneya on a heavy, wet soil. ly the annual stems die off in the winter and be cut down at ground level in the early ; if persistent the stems can be cut back to growth. The new growth is susceptible to amage, and appropriate steps must be taken *Prop.*—Seed or suckers taken off in the .

a (Rose).—Undoubtedly the rose is the most ar of all garden flowers, and it may be found multitude of forms. The dwarf roses for ng may be grown on most soils, but are best rich, heavy loam. Planting is done from November onwards when soil conditions t and the first pruning carried out in the ing spring, when the extent of any winter ge can be seen. Opinions differ sharply on g; a sound, general rule is to do the work rch and—unless there are special circum- es—to prune on the light side. Thus, for d Teas and the like, reduce strong stems by one-third of their length, medium ones by a nd weak ones to within two or three buds of ain stem.

atever sorts of soil roses are grown in, feeding ortant, but, of course, it is particularly so on ones. It is in soils of *low* fertility that es such as rust and black spot are most pre- , and, in some measure, persistence of the e is due to bad cultivation and lack of treat- with fertilisers. Where black spot is estab- essential, and a selection list may include: *Hybrid Teas:* 'Christopher Stone' (crimson), 'Dame Edith Helen' (pink), 'Eden Rose' (magenta pink), 'Granmere Jenny' (yellow, rose-pink flush), 'Madam Henri Guillot' (salmon pink), 'Quebec' (yellow), and 'Tzigane' (bicolor; vermilion and yellow). *Floribundas:* 'Dainty Maid' (rose pink), 'Dusky Maiden' (dark red), 'Tantau's Surprise' (deep crimson), and 'Yellow Holstein' (yellow).

In most of the modern hybrids scent is almost absent. The true rose perfume is found only in the Old Fashion or shrub roses and, normally, these are planted in a mixed shrub border. For the richest perfume varieties like 'Mrs. John Laing' and 'Conrad F. Meyer' should be sought. *Prop.*—Nurserymen's plants are budded; many varieties are easily raised from cuttings taken in the autumn and struck in sandy soil out-of-doors.

Salvia.—Annuals, perennials, and tender shrubs. The most popular one is the scarlet sort used for bedding. It requires careful attention, and seed should be sown in February in a temperature of 60° Fahrenheit and seedlings put into single pots when large enough. Gradually the young plants are hardened off and finally planted out in rich soil in a sunny bed.

Saxifraga.—A large genus of plants suitable for the rock garden and valued for their bright flowers in the spring. The encrusted saxifrages are cushion-forming plants requiring sharp, surface drainage and an open position out of the direct

sun. The mossy saxifrages are mat-forming in growth and of easy culture. In time old clumps develop brown patches and then require splitting up and replanting in the spring.

Scabiosa.—The commonly grown perennial sort is *S. caucasica* and is invaluable as a cut flower. It is not at home on all soils, and only does really well in a deep, rich loam containing plenty of chalk. In addition, it must be grown in full sun and particular care taken against slugs. *Prop.*—Old plants divided in the spring and rooted pieces replanted in their flowering positions. A wide range of shades in white, blue, and purple can be had normally from sowing mixed seed in April.

Sedum.—The stonecrops make up a large group of hardy and tender plants, but comparatively few are of horticultural value. Notwithstanding, *Sedum spectabile* is to be found in most herbaceous borders, where its fine, flat heads of pink flowers are a feature for many weeks. It is beloved by bees and butterflies. *S. sieboldii* was introduced from Japan about 100 years ago and, although hardy, it is usually grown as a house plant. In the winter it can be stood out-of-doors, and every two or three years repotted in the spring; keep well watered during the summer and feed with liquid manure occasionally. *Prop.*—Division in the spring.

Sempervivum (House leek).—These hardy plants with succulent leaves often decorate the crevices of old walls and are regular features of trough or sink gardens. If given a light, poor soil and a position in full sun a fascinating collection of house leeks can be built up. The species which gives the plant its common name can be established easily on a sunny roof by planting in a mixture of cow manure and clay during the spring. *Prop.*—Division in the spring.

Skimmia.—A hardy evergreen 2–3 ft. tall which is tolerant of shade and some degree of dryness. If growth is poor water with a liquid manure and mulch with peat or leaf mould. Some forms bear only male flowers and to ensure a good crop of berries plant an hermaphrodite like *S. foremanii*. *Prop.*—Layering in the autumn.

Snowdrop.—*See* Galanthus.

Snowflake.—*See* Leucojum.

Solanum capsicastrum (Winter Cherry).—A berrying plant with bright-red fruits which is often used for house decoration. To maintain the plant in a healthy condition it should be clear of draughts and fumes of gas fires and the foliage kept fresh and free of dust by vigorous syringing. If the stock is to be kept for more than one season water should be given only sparingly in the New Year, and in early March all the side shoots pruned back hard to within a bud or two of the main stems. As new growth develops, water can be given more freely and syringing started when the flowers first appear; liquid manure will prove beneficial when berries develop.

Spiraea.—Hardy deciduous shrubs for open borders; tolerant of poor soil conditions. The commonly grown one is *Spiraea bumalda* (syn. *japonica*). After flowering, a percentage of the old wood should be removed together with any weak growth, and development of new shoots encouraged by mulching with compost or animal manure. *Prop.*—Cuttings rooted in sandy soil under a hand light in summer; suckers thinned out in winter.

Stocks.—*See* Mathiola.

Sunflower.—*See* Helianthus.

Sweet William.—*See* Dianthus.

Symphoricarpos (Snowberry).—Often found existing in deep shade and in competition with roots of overhanging trees, presumably as a result of the generalisation that the shrub is a shade lover. Certainly a useful one in this respect, but it is responsive to good treatment. Given an average soil and if growth is thinned annually in the early spring, then *S. albus* 'Laevigatu well worth having. Its large white fruit untouched by birds and hang well into the w and are thus beloved by the floral deco *Prop.*—Suckers removed in the winter.

Syringa (Lilac).—The botanical name of *S* is often erroneously applied to the Mock O correctly named *Philadelphus* (*q.v.*). A selection of first-class varieties are availal nurserymen's lists. To obtain heavy cro flowers nip off all dead flower-heads as the som fades, but do *not* cut back into the old as this will prevent flowering. At the same any branches causing overcrowding can b moved. Annually feed with "National moro" at 2 oz. per sq. yd. and on poor soils with any sort of manure or compost. *P* Layering in the autumn.

Tagetes (African and French Marigolds).— hardy annuals of free-flowering habit and culture. Best if fed generously with soot wa other nitrogenous manure during growing s *See* Annuals.

Tropaeolum.—The common nasturtium a flame flower (*T. speciosum*) belong to this The former is easily grown from seed sown i in a sunny position. The latter is a very di plant to grow outside the conditions wh demands. To be successful, this perennial cl must be planted in acid soil which is nat damp and lightly shaded but yet where th growth can reach full sun. Much disappoin often results from planting it in eastern En for instance, after seeing it flourishing almos weed where the rainfall is high in Ireland a west of Scotland.

In the genus will also be found the c creeper, which can be used for screening pu and will thrive in full sun or shade. Seed is in May in open ground and light supports su by way of pea sticks or strings; failure is no due to nothing more than lack of moisture.

Tulipa (Tulip).—Thrives in a deep, rich but will do well for one season in ordinary g soil. When used for bedding, bulbs must be after flowering, replanted in a trench, thoroughly watered. Sometimes tulips m left in the ground if conditions are favou and then the stock only needs lifting and re ing every three years. To check the incide tulip fire plant in late November or early D ber, covering the bulbs with 4–5 in. of so treat the ground with a fungicide like "Bot Before doing so rake in a dressing of 2 oz. phosphate and 1 oz. sulphate of potash per s yard. A small collection of wild tulips is got together at Cambridge and grown there University Botanic Garden.

Viola.—This name embraces pansies, viola violets. Although the viola has not got th colours of the pansy (or its attractive mar it has got a remarkably long season of flowe for this reason it is invaluable as an edging or as ground cover for roses. *Prop.*—Both are easily raised from seed sown in a frame spring, pricked out, and then transferred to flowering positions in late May. Alternat seed may be sown in July for planting October. Named varieties increased by cu in a frame in late summer.

Virginia creeper.—*See* Parthenocissus.

Wallflower.—*See* Cheirianthus.

Water Lily.—*See* Nymphaea.

Winter Sweet.—*See* Chimonanthus.

Wistaria.—One of the finest of all cli plants for south or west walls or stout pe Plants which do not flower, or only do so p are probably seedlings and the true flowerin cannot be induced; the only solution is to r with a *grafted* plant of known flowering ca from a reliable nurseryman. All young not required for the extension of branches be shortened to within 3 in. of the old stem

tumn. Wistarias growing over trees do not quire pruning. *Prop.*—Layer shoots of current ason's growth in the autumn.

Zinnia.—Half-hardy annual, ideally grown on oist, deep loam liberally enriched with well-cayed manure. Mulch with manure after anting and apply liquid fertiliser as buds appear; ants must not suffer from lack of water. *See* nuals.

MAKING A LAWN

In almost every garden the most prominent ature is the lawn, and often a lot of work is put o making one without any great measure of ccess. Usually, the reason for failure may be nd in faulty preparation of the soil or premature wing, albeit the blame is often placed on bird mage or poor seed.

For anything like a reasonable turf, the site ist be thoroughly dug and the content of ganic matter increased by incorporating gener-s quantities of materials like peat, leaf-mould, mpost, sewage sludge, and animal manure. A ressing of these ingredients can be applied in a ver 3–4 in. thick and buried in the bottom of the o spit of soil. As the ground is dug to incor-rate the organic matter, roots of perennial eds should be removed.

If the site is one on which water tends to lie or the soil is heavy, then surface drainage should sharpened by forking into the top 2 or 3 in. a eral application of some coarse material such as lders' rubble, road grit, screened ashes, or arse sand. In some cases this treatment will t be sufficient, and then the installation of land ains must be resorted to. This particular task not as difficult as is sometimes imagined, but, fore a start is made, it is always a good plan to cuss the matter with an experienced man.

After the initial work a fine tilth on the soil may obtained by thoroughly raking and cross-raking d at the same time establishing a level surface. this point, it should be remembered that good ns can be made on undulating ground or on tural slopes, but the things to avoid are the llow depressions where water will naturally d to lie. Finally, ten to fourteen days before wing the subsequent growth of grass can be couraged by making an application of " National owmore " at 2 oz. per sq. yd.

Sowing is best done in the late summer at a time nen the soil is moist For the purpose, a good xture of seed should be obtained from a reliable edsman, and it is worth paying a reasonable ice for it, as, by and large, the coarsest and ighest grasses have the largest and heaviest eds. Opinions differ on rates of sowing, but, th care and in a well-prepared soil, 1 oz. per yd. is ample; heavier rates may give quicker sults, but the density of seedlings in such cases en leads to the finer grasses being choked by e coarser ones.

After sowing, the ground should be lightly red, but not rolled. At this stage the important int is to protect the seed bed from birds by the e of hazel sticks, strings of papers tied to stakes er they have been dipped in lime-wash, and ands of black cotton. Subsequently, annual eds may appear in quantity; these are of no nsequence, and they will be eliminated once the ass is cut regularly. Until a good turf is formed usually about twelve months after sowing—it not desirable (or probably necessary) to use rmone weed-killers. *See* T33.

Care of Established Lawns.

Most turf is never manured from year to year, and the soil may seriously lack plant foods. In the first place this can be corrected by making an application annually in the spring of " National Growmore " at 1 oz. per sq. yd. Subsequently, if growth is below par in the early part of the year an application of sulphate of ammonia can be made at the same rate. To avoid scorching or blackening of the foliage, each fertiliser can be mixed with equal parts of dry soil or sand as a carrier to ensure even distribution and, what is most important, each one should be applied only when the turf is wet and there is the prospect of rain to follow. Linked with this treatment, turf is always responsive to top dressings. A compost for the purpose can be made up with:

2 parts of loam;
1 part of sieved compost;
1 part of fine peat or leaf soil.

This may be used in the spring at 3–5 lb. per sq. yd. and if the soil is heavy 1–2 parts of gritty sand may be added.

With the introduction of new designs in motor mowers, most lawns are seriously overcut, and this has led to a sharp decline in the quality of the grass and the appearance of one or two pernicious weeds. It is appreciated that special turf, such as that found on a bowling green, may be shaved off to ¼ in., but if a utility lawn is cut below half to 1 in., then the quality of the grass will deteriorate. Of course, it is a good thing to occasionally cut the grass very short, but, conversely, if the blades of the mower are set as low as possible and left like it throughout the season nothing but harm can result. The reason for this hard fact is that when the turf is cut very close the grasses simply cannot develop and spread, and weeds will gradually establish themselves. Eventually the cultivator will be faced with the difficult problem of trying to deal with such plants as pearlwort, yarrow, and various mosses, all of which are resistant to hormones.

As for the vexed question of whether or not to remove the mowings, there is no doubt that the best turf is found where the mowings are collected up, although in very dry weather they can be left on the surface. If the clippings are not removed the surface of the turf tends to become choked with semi-decayed organic matter, and conditions are brought about which are inducive to the spread of moss.

Finally, it is worth noting that the finest turf is found on acidic—not alkaline—soils. For this reason, lime should not be applied as a general rule, for apart from helping the development of coarse grasses, it encourages the growth of clover. Of course, there are times when lime is necessary, but the occasions are rare and before it is used it is a good plan to test the soil by chemical means.

THE FRUIT GARDEN.

The guidance of an expert is probably more important in the growing of fruit than for most of the commoner vegetables and ornamentals. This is primarily because the majority of fruit trees and bushes are long-lived, and only in the case of strawberries can a change of site or variety be made easily and inexpensively.

Gardens which are low-lying are very prone to damage from spring frosts, and should not have too much space devoted to fruit, as returns may well prove unprofitable. Here, as with the selection of varieties, advice of a local expert is invaluable. Some varieties do better in certain localities and on certain soils than others, although personal preferences will naturally be met where possible. Varieties chosen should cover as long a season as is practicable so that the fruit can be used and enjoyed to the full.

Tree fruits are grown on a rootstock, and for apples and pears special dwarfing stocks make these a possibility for the small garden. It is therefore important to explain to the nurseryman what type of tree is required. As a general rule, however, the smaller gardens will gain by concentrating on currants, gooseberries, raspberries, and strawberries. Plums and cherries have no

dwarfing stocks, and should be included only where sufficient room is available.

Adequate preparation of the ground is important, and this, followed by good management, can result in worth-while crops from most soils, providing they are reasonably free of frost, well-drained, and sufficiently sunny.

Apples.—Can be grown on most soils. Manure should not be used when planting, except in sandy and chalky gardens. Obtain trees on dwarfing rootstocks, such as M.IX, M.VII, or MM.106. Always stake trees on M.IX, otherwise this practice is necessary only in exposed sites. The tie must be rigid, with a " cushion " between tree and stake to avoid chafing, and must be renewed annually to avoid constriction. Plant between late October and early March, preferably before Christmas if soil and weather allow. Make the hole large enough to spread the roots evenly; firm thoroughly while filling in and plant level with the nursery soil mark already on the tree. Mulch around each tree with manure or compost, mainly to avoid drying out, and supplement with watering during the summer when necessary.

In the first year any flowers produced are best pinched out to encourage root and shoot development. For walls or fences use oblique cordons or espaliers; these are also useful for flanking paths and lawns. Plant cordons 2½ ft. apart with 6 ft. between rows, and espaliers 12–15 ft. apart. For larger areas use bush trees 12–15 ft. apart.

Manuring for cropping trees should be varied according to growth. Generally apply 1 oz. sulphate of ammonia (or nitro chalk on acid soils) in early March, repeating this in early April if trees are growing in grass. Give ½ oz. sulphate of potash in February and add 3 oz. of superphosphate every third year. The above rates are per square yard, and a complete fertiliser can be used in lieu if preferred.

Young bush trees should have main shoots reduced by half in early years to produce strong branches. Thereafter prune side shoots to three to six buds. For weak growers prune harder, and for strong growers prune less. It is wiser to leave a strong tree unpruned than to prune it too severely, the latter merely encouraging even stronger growth. A few varieties (*e.g.*, 'Bramley's Seedling,' 'Worcester Pearmain') fruit at shoot tips, and here a proportion of side shoots should be left unpruned. Summer pruning is advisable on restricted trees, such as cordons; for details see pears. Very few varieties are self-fertile, and at least two sorts should be planted to ensure satisfactory crops. Good combinations are 'Cox's Orange Pippin' with 'Laxton's Fortune' and 'Winston' with the cooker 'Lord Derby.' Seek expert advice on pairings if in doubt.

Apricots.—These are often an unreliable fruit to grow, needing a well-drained, calcareous loam and a warm wall for success. Train the tree as a fan, and once established pinch unwanted side shoots to four leaves in summer. Thin fruits when young, these developing mainly on spurs on older wood. 'Moor Park' and 'Hemskirk' are good varieties.

Blackberries.—Allow plenty of room and train against fences or wires. Autumn planting is preferable, using good, well-manured soil and cutting back the cane to 9 in. from the ground. Mulch with manure each spring, water freely in drought, and cut out old canes as soon as they have fruited. Good varieties are 'Himalaya,' 'Merton Thornless,' and the parsley-leaved blackberry. Increase by tip layering.

Cherries.—Sweet cherries are unsuited to most gardens. The trees become too large, and *must* be planted in selected pairs to fruit satisfactorily, as all varieties are self-sterile. Large wall spaces are ideal for fan trees, as the fruit can then be protected from birds by the use of nets. Pinch side shoots on fans to four leaves in July; further pruning details being as for plums. Expert advice is essential to ensure that suitable varieties are grown together, the factors involved being complicated. 'Early Rivers' with 'Bigarr Schrecken' and 'Merton Heart' with 'Water are good combinations.

For the small garden the dwarf-growing, 'Morello' cherry is more useful, being infini superior for preserves as well as self-fertile. also succeeds on a north wall, but unlike sw varieties, fruits *only* on one-year-old wood.

Currants, Black.—These are perhaps the m valuable of all hardy fruits, and bushes will up to 10 lb. and more of currants with cor treatment. Plant from November to Febru preferably autumn, at 5 ft. square on cl heavily manured ground. Then cut all shoot one bud above soil level. Mulch each spring w well-rotted manure and supplement with fertili if necessary. The mulch is essential as much keeping the soil moist as for a general feed.

On established bushes prune preferably a fruiting or in winter, retaining strong young w and cutting out older shoots, where possible f ground level. If necessary, alternate bushes be cut down completely every other year to m tain vigour, as the bulk of the crop is always be on young wood. Increase by 8-in. cutting one-year-old wood taken in late September f healthy bushes. Remove lower leaves and in firmly with one bud above ground. Good va ties: 'Boskoop Giant,' 'Wellington XX 'Baldwin.'

Currants, Red and White.—One or two w grown bushes are usually sufficient for the ave household. Plant between November and Mi at a minimum of 4 ft. square on well-maint ground and mulch each spring. Supplement w fertilisers if necessary, potash being particul important in the form of sulphate of potash at per sq. yd. in February. Can be grown as cord or fans against walls or fences, on which the pi ing of young side shoots to four leaves in mid-J is essential. Winter pruning of all types sim involves cutting side shoots to one bud and pruning branch leaders. Propagate by 1 cuttings of young shoots in late September inse to half their length with all buds removed ex the top four. This enables the bush to be gr on a "leg." A permanent framework of bran is then developed, as, in contrast to the b currant, fruit is borne on spurs on the old w Good varieties: 'Laxton's No. 1,' 'Red La 'White Grape.'

Damson.—*See* Plums.

Figs.—A warm south wall is usually essen 'Brown Turkey' being one of the few reli outdoor varieties. Plant in a brick or conc trough (with drainage holes) about 2½ ft. w 5 ft. long, and 2½ ft. deep so that the root ru restricted. This will curb excessive gro (which otherwise is difficult to control) and courage fruiting. Plant in March for preferen to avoid frost injury to young shoots, and t train fan-wise. A rich soil is not essential. visible as such in the autumn will never c winter, and should be rubbed out. Those size of a pea and less at the tips of short, w ripened shoots, on the other hand, are the po tial crop for the following year, and should covered in severe weather to avoid frost dam To encourage the formation of these embryo fi pinch young shoots back to the fifth leaf in August. Winter prune in March, removing wood that is frosted, overcrowded, or worn growths should be spaced at about 1 ft. App spring mulch and water freely when require avoid premature fruit drop.

Gooseberries.—Need conditions and spa very similar to red currants, but with rather m moisture to ensure ample new wood, as this b fruit as well as the older wood. Apply sulpha ammonia and sulphate of potash annually in February at up to 1 oz. per sq. yd. of eac addition to mulching. Can also be grown cordons, etc., as for red currants. Prunin also similar, though not quite so severe, as young wood is productive of fruit. Cuttings more difficult to root, and for best results sh

taken in mid-September, again as for red rants. Good varieties: 'Lancer,' 'Leveller,' Thinham's Industry.'

Grapes.—Outdoor vines should be grown against varm south- or south-west-facing wall. With od cultivation, the grapes should then ripen cessfully providing suitable varieties are osen. In preparing the site ensure that it is ll drained and break up the soil to a depth of out 2 ft. Add bone meal to the top few inches 4 oz. per sq. yd. and incorporate mortar rubble, rticularly on the heavier soils. Do not dig in y manure except on poor, light soils, but always ply some as a mulch after planting, repeating s every spring. On poor, hungry soils the im- rtation of some fibrous loam is advisable where ssible.

Plant in November or, failing this, before early rch, with the stem about 6–9 in. away from the ll. Firm well and then wait a further two nths before tying to any wires or stakes, in se of soil shrinkage. Cut the vine back in winter well-ripened wood and to just above a bud. e training of subsequent growth will then pend on the space available, single and double rdons being the most convenient. Unwanted oots should be pinched at about 2 ft. in summer d leading shoots carefully tied in to wire bamboo supports. The following winter ecember) prune leading shoots back to well- pened wood so as to leave 3–4 ft. of new growth. en cut all laterals hard back to one bud. In ring reduce young side shoots to one at each d, stop laterals at about 12 in., and pinch any b-laterals that may develop to the first leaf. not allow any crop to develop, except perhaps e bunch if growth is adequate; others should be nched off. As fruit develops, thinning should done as required. Winter prune as before, d then in the third summer four or five bunches grapes can be allowed if the vine is healthy. e crop then increasing annually. Shoots carry- g bunches should be pinched to two leaves yond the bunch. Winter pruning is repeated ch year as already described. Sour top-soil ould be carefully removed when necessary and placed with good loam while the vine is dormant. ood varieties: 'Black Hamburgh' and 'Foster's edling.'

Loganberries.—A very popular hybrid berry hich should be treated as for blackberries. A ornless form is now available. Suitable for a rth wall.

Medlars.—A tree of spreading habit, the peculiar uits of which are best used for jelly before they e fully ripened. Most soils are suitable, and no uning is needed except to keep in shape.

Nectarines.—A fruit very closely allied to the ach but with a richer flavour and needing rather ore warmth. The skin is smooth, as distinct om the hairiness of the peach. For full details e Peach.

Nuts.—The most important kinds grown are obnuts, the closely related filberts, and walnuts, t none of these is cultivated to any great tent. The two former kinds flower very early February, and are therefore predisposed to frost mage; similarly, the young shoots of walnuts e easily injured by spring frosts, and all are erefore inadvisable for frosty areas.

Cobnuts and filberts.—Highly developed forms the ordinary hazel nut. The nut of a cob is ly partially covered by the husk, whereas a bert is completely enclosed by it, this being e essential difference between the two. Will ow on most soils, including the poorer ones, and acing should be about 15 ft., choosing sites shel- red from the colder winds. Plant during the tumn. Prune established bushes in March, tting back shoots that have borne nuts to two three buds; strong young shoots are cut back a catkin near their base, and the weaker ones e left untouched. In August any strong new de growths are "brutted"—that is, broken off— nd left hanging until the March pruning. Gather ne nuts as they fall and allow to dry. Then store in jars for Christmas use, packing salt and coconut fibre between each layer of nuts.

Walnuts.—Special, grafted varieties are now available which produce early crops compared with the unreliable seedling trees that used to be planted. Plant between October and March and water well in spring and summer. Do not prune, as walnuts bleed badly. Gather nuts in mid-July for pickling. For storing allow to drop naturally and remove outer husk immediately, scrubbing the shell clean and then drying thoroughly. The shells can be bleached if necessary before storing the nuts as for cobs above.

Peaches.—This fruit along with its close ally, the nectarine, is best grown against a warm south or south-west wall, but two varieties of peach, 'Peregrine' and more particularly 'Rochester,' will succeed as bushes in the open in southern England. The fan-trained peach is one of the most difficult trees to keep in order, as sufficient new shoots must be retained annually to replace old wood. This is essential, as it is only the previous year's shoots which bear fruit. Badly placed shoots are rubbed out when only an inch long, and the principle is to allow one young replacement shoot to develop near the base of each fruiting shoot, pruning back to the former and tying it in as soon as all fruit has been picked. Other shoots may be used to extend the fan where space allows or to replace any branches or parts of them which may have become worn out. Other unwanted shoots are bound to arise during each summer, and these are either removed immediately or pinched to three leaves and then removed when pruning in late summer. These shoots retained are spaced about 4 in. apart.

Most peaches are self-fertile, but hand-pollinating on sunny days can improve the set. Excessive feeding should be avoided, varying this according to each tree's performance, but as a general rule a surface mulch of well-rotted manure or compost should always be given each spring, together with sulphate of potash at ½ oz. per sq. yd. Prick over and rake off top-soil and replace with good loam every few years. Never allow the sub-soil to dry out—this can quickly occur against warm walls—and water thoroughly when doing so to ensure an even distribution of moisture. On the other hand, drainage must be satisfactory to avoid waterlogging.

There are numerous other essential operations in the growing of trained peach trees (for example, fruit thinning), and it is impossible to deal with these adequately in brief notes. Would-be growers should therefore seek expert advice and obtain literature dealing specifically with the crop rather than risk disappointment. Good varieties for outside wall training include: *Peaches:* 'Peregrine,' 'Bellegarde.' *Nectarines:* 'Early Rivers,' 'Lord Napier.'

Pears.—The requirements for pears are similar to those for apples, but the necessity for adequate summer and autumn warmth rules out many varieties for northern areas. In these less-favoured localities enquire which varieties do succeed, and where possible make use of a warm, south-facing wall. Protection from wind is very important, particularly from the cold easterlies of spring. Many soil types grow pears satisfactorily, providing drainage is good and the trees are looked after. Plant as for apples. Fertiliser requirements are also similar once cropping commences, except that pears may require a little more nitrogen.

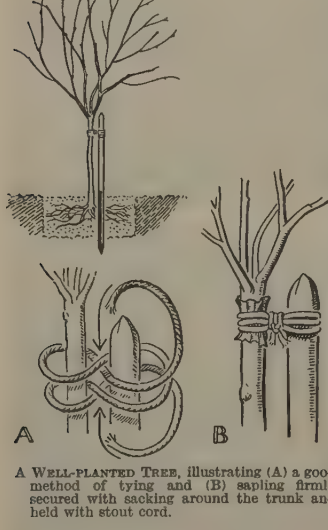
Pruning (winter) is comparatively simple, the spur pruning given for apples suiting all except a very few pears. Initial shaping is essential, cutting the stronger shoots selected to form branches by about half their length and keeping the centre of the tree open. For cordons and other restricted forms of tree, to which pears lend themselves particularly well, summer pruning is advisable. This involves shortening all young shoots more than 10 in. in length to about 5 in. from the base. Do this when the base of such shoots is hardening and turning brown in colour, usually late July–early August. Pruned shoots may then be further reduced in winter. Such summer treatment may also be given to trained apple trees with advantage during August.

Only a few pears are self-fertile and 'Con-

ference' is the most reliable if only one tree can be planted. Good pollinating pairings include 'Laxton's Superb' with 'Doyenné du Comice' and 'Conference' with 'Williams' Bon Chrétien.' Early varieties should be picked a little before ripening and used quickly.

Plums.—This general term includes gages and damsons. Numerous varieties are easy to grow but are unsuited to small gardens because of the amount of space required. Unlike apples and pears, there are no dwarfing rootstocks, and a minimum spacing of 14 ft. should be allowed for, growing the trees as half standards, or fan-trained against a south or west wall. Flowering is during April, and frost damage can be serious in some seasons. Plant preferably in the autumn, and by early March at the latest, using no manure unless soil is distinctly poor. Young trees should be staked during their early years, and must not be allowed to rub against the support.

Pruning should be reduced to a minimum, as the spores of silver leaf disease gain entry through wounds such as pruning cuts and stake rubs. Shorten branch leaders on young trees just as buds are bursting, but on older trees prune only when branches become overcrowded. Do this between June and August, when the risk of silver leaf is at a minimum. Cut cleanly and coat the wounds thoroughly with a bituminous paint; treat broken branches similarly immediately they are noticed. Trees fruiting heavily should have the branches supported and the fruit thinned in late June. Side shoots on fans must be cut to four to five leaves in late June and reduced still further following picking if necessary. Feed cropping trees regularly to encourage new growth, using well-rotted manure or sulphate of ammonia at 1 oz. per sq. yd. in early spring. Some varieties are self-fertile including 'Victoria,' 'Oullin's Golden Gage,' and 'Merryweather Damson.'



A WELL-PLANTED TREE, illustrating (A) a good method of tying and (B) sapling firmly secured with sacking around the trunk and held with stout cord.

Raspberries.—These are an ideal fruit for the small garden, but because of virus disease always buy certified canes from a fruit nursery. Plant between November and March on clean, well-manured ground, allowing 18 in. between canes and 6 ft. between rows. After planting prune each cane back to 12 in. Do not attempt to c them in their first year, or the production of yo canes for the following year's fruit will suffer.

A semi-shaded position will answer, but full is preferable for quality fruit. New canes sho be looped with string to a post-and-wire fence later tied individually to each wire when f hardened. Space them at about 4 in. and rem any weak or diseased canes at ground level. late February cut each cane to just above the wire, which is usually 5–6 ft. high. This remo any damaged tips and may encourage fruiting a longer length of cane. In the second summe fair crop should result, and netting against b is essential. Regular watering is imperative dry weather, and spring and summer mulche well-rotted manure or compost should always applied. Supplement this in March with nitro and potash (fertilisers) if required, this depen on how well the ground was manured before pl ing. After fruiting cut out all old canes and in the new ones as already described. 'Mal Promise' and 'Lloyd George' are good varieti

For autumn-fruiting varieties prune all ca to the ground in late February and tie in the during the summer for cropping in Septemb October. 'September' is a good variety. 'Lloyd George' can also be used.

Strawberries.—This is the one fruit that sh be included in the vegetable garden. F ground can then be used regularly for establis new beds. Plants more than two years old seldom profitable, and the best fruit is alw picked from healthy one-year-olds planted previous August or September. Runners pu later than early October should be deblosso the following spring, the reward being a m heavier crop in the second year. This wa ground, however, and early planting is prefer on all counts. Prepare the ground well in adva of planting and dig in plenty of well-rotted ma or compost or both, as this is the key to succe

Because of virus diseases order certified pl from a fruit nursery and burn any unhealthy in old beds before planting. Insert firmly the base of the crown of each plant just at level and refirm after winter frosts; space 20 in. in rows and 2 ft. 6 in. between rows (3 possible). A mulch of rotted manure or com is beneficial each autumn, and if this is lac apply sulphate of potash at 1 oz. per sq. yd. stead. Bonemeal is also advisable in spring again in July, but quick-acting *nitrogenous* tilisers should normally be avoided.

During flowering cover the plants where poss to guard against frost damage reducing the c Keep the ground weed-free and remove run regularly; a few plants should always be gr away from the main bed, deblossomed and purely for runner production, as this then h to reduce the spread of virus. Ruthlessly any plant that remains stunted, including runners, as this is usually a symptom of v disease. When the young fruits are just form spread clean straw underneath them to a splashing from the soil; it is a mistake to do too early, as it increases the risk of frost dam Net the fruit against birds and remove any rot specimens when picking.

After fruiting remove and burn all old foli weeds, and straw, and feed as already descri Plant a percentage of new, vigorous runners year on fresh ground, at the same time bur the old ones they are replacing. Good vari include 'Royal Sovereign,' 'Cambridge Favour and 'Talisman.'

Alpine strawberries require similar treatm preferably with a semi-shaded position, and sh be raised from seed. Perpetual fruiting t continue fruiting on and off well into the autu and should be treated as for ordinary varie In all cases cloches can be used from late Febru onwards to obtain early fruit.

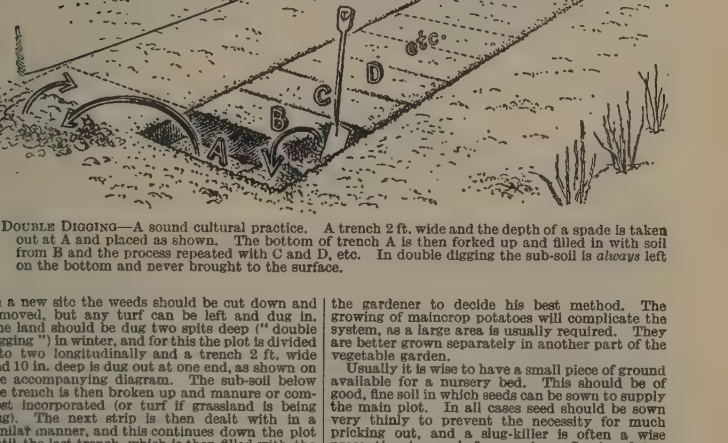
THE VEGETABLE GARDEN.

The vegetable garden is, or should be, an integral part of home economy nowadays. Home-rown vegetables, although requiring considerable bour, are cheaper and fresher than most shop pplies. The ideal site is in an open, sunny osition sheltered from cold winds with the soil deep, rich loam well supplied with humus; ite obviously very few gardens have the ideal te, and we have to do the best we can with the ound available. In laying out the vegetable ot, ease of working should be considered; the nes of vegetables should go from north to south, d paths should be wide enough for a barrow to ss. The vegetable lines should not be too long, the soil will be trodden down too much.

Each individual will have to decide the size of s plot according to the amount and types of egetables required, and the land available. helter from a hedge or wall is desirable, and a ot about 90 ft. by 30 ft. can be made to produce succession of vegetables to feed an average family er the year. Land preparation is important; the carry-over of some pests and diseases and providing for a full use of the manures in the soil, as different groups of vegetables need more of some nutrients than others. It also allows the clearance of one section to enable winter digging and manuring to be carried out. On this freshly manured plot peas, beans, onions, leeks, and lettuces, all revelling in rich ground, should be grown. The next plot, manured for the *previous* crop, can be used for root crops—early potatoes, carrots, parsnip, and beet. A light dressing of artificial fertiliser such as "National Growmore" should be applied before sowing. On the third plot the green vegetables should be grown; a dressing of fertilisers is desirable, and lime should also be applied.

In the following season the root crops can be grown on the plot which was manured the previous year, and the brassicas grown on the land vacated by the root crops. The plot on which the brassicas were growing is double dug and manured ready for the peas, beans, and onions. A system of this type proves very satisfactory, but numerous variations can be devised, and it is really a matter for



DOUBLE DIGGING—A sound cultural practice. A trench 2 ft. wide and the depth of a spade is taken out at A and placed as shown. The bottom of trench A is then forked up and filled in with soil from B and the process repeated with C and D, etc. In double digging the sub-soil is *always* left on the bottom and never brought to the surface.

a new site the weeds should be cut down and moved, but any turf can be left and dug in. he land should be dug two spits deep ("double gging") in winter, and for this the plot is divided to two longitudinally and a trench 2 ft. wide d 10 in. deep is dug out at one end, as shown on e accompanying diagram. The sub-soil below e trench is then broken up and manure or com-st incorporated (or turf if grassland is being g). The next strip is then dealt with in a nilar manner, and this continues down the plot ntil the last trench, which is then filled with the oil from the first trench.

Clay soils which are sticky are much improved humus and constant working, but should not dug in wet weather. Sandy soils also require nty of humus to conserve moisture, but are less rtile, though often warmer and earlier. For e majority of vegetables a slightly acid soil is st, and a dressing of lime is only desirable if the il is too acid. Double digging is not necessary ch year, and single digging, carried out in a nilar manner without breaking up the second it, or a light forking over is sufficient for some ops, provided the ground has been well cul-rated previously.

The lay-out with vegetables must be designed provide a succession through the year and to ilise the full capacity of the ground by catch ops and a suitable succession. The land can be vided into four plots: one is used for the more less permanent crops, such as asparagus, rhu-rb, and globe artichokes, and the other three ll provide a rotation. This is used to stop any oup of vegetables being grown on the same lan.' ore than once in every three years, so preventing the gardener to decide his best method. The growing of maincrop potatoes will complicate the system, as a large area is usually required. They are better grown separately in another part of the vegetable garden.

Usually it is wise to have a small piece of ground available for a nursery bed. This should be of good, fine soil in which seeds can be sown to supply the main plot. In all cases seed should be sown very thinly to prevent the necessity for much pricking out, and a slug-killer is often a wise precaution to use before sowing. Sowing dates, as given, are mainly for growers in the South. In the North sowing dates in spring will be generally two weeks or more later and autumn operations the same amount earlier. Any gardener must adjust his work to suit local conditions of soil and climate, and this knowledge is only gained by experience of the particular area.

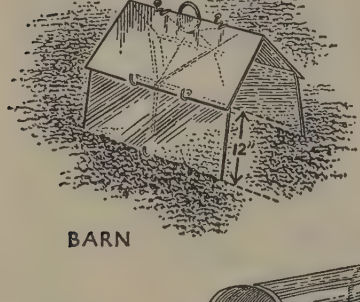
General cleanliness in the vegetable garden is at all times desirable; weeds and rubbish only harbour pests and diseases, and the hoe should be busy whenever possible. Waste material can be utilised in that essential of the modern garden—the compost heap. *See* Manures and Fertilisers for description.

Frames and Cloches.—The gardener is able to extend the season of many crops by protecting them under frames and cloches; this is particularly useful where spring or early autumn frosts are prevalent. The use of frames is limited, as they are in a fixed position, but nevertheless they are very useful for obtaining out-of-season salad crops, especially if they are heated by electricity or a hot bed.

Cloches have the advantage of mobility and can be used on a number of crops in succession. Essentially, each is a number of pieces of glass in a tent or barn shape held together by wire. Pattern, size, and height vary according to the crop to be covered and the manufacturer's design. A good cloche should be of simple design, rigid and capable of standing up to ordinary winds, easily transported, and well ventilated.

The low barn cloche is probably the most economical type. This is 23 in. wide and 13 in. high when erected, and will allow two rows of lettuce to be grown, with an intercrop of another vegetable. The large barn or barn cloche of similar design, but with 12-in. side is 19 in. high in the centre, enabling taller crops, *e.g.*, peas and dwarf beans, to be grown on, almost to maturity.

Dwarf varieties should be used for grow under cloches, although methods of raising cloches another foot or so have been devised are on the market, which allow the use of ta growing varieties. Many different vegetables be helped to some extent in the early sta besides those crops which can be grown enti under cloches; the grower must decide what cr he needs and it a rotation to cover as many cr as possible with the cloches available. This mainly a matter of experience, but books on subject will suggest many variations that can tried. Intercropping with quick-maturing cr can also be practised. As instances, radish mustard and cress can be cropped between rows of lettuce, or a row of cos lettuce can be gr between two rows of cabbage lettuce.



TYPES OF CLOCHES—The most popular is the barn cloche; with 12-in. sides it will cover strawber and peas and beans in their early stages. The low barn will accommodate three rows of let in winter and cucumbers in the summer. Plastic cloches are growing in popularity, especi those patterns using toughened plastic, and have some decided advantages over glass ones.

The tomato cloche has sides 24 in. square and a basal width of 26 in. Many others of various shapes and sizes are offered; the amateur should buy to suit his own requirements. Other materials have been tried instead of glass with varying success. Plastic cloches are on the market, but their lightness entails very safe anchoring, and at the moment glass still seems to be the best material in most instances.

Gardening under cloches obviously is a subject too large to be dealt with in a few sentences, and the reader would be well advised to refer to one of the books mentioned in the bibliography for fuller information. A few of the main points are mentioned here and also under the individual crops.

Cloche cultivation is an intensive method of production, and this means that the land must be well cultivated and manured to ensure good-quality crops at all times. About ten days before crops are sown or planted the cloches should be put in the position where they are to be used, to warm the soil. The crop is sometimes sown a month before the normal date, and this prewarming ensures that the soil can be cultivated to a good tilth, as well as giving the plants a good start. Watering is a problem that often bothers the amateur. Provided the soil is well watered at sowing time, there should be no need to decloche to water. Rain seeping under the cloches and a spray directed over them occasionally will provide enough for the crop in normal weather; on dry, sandy soils it may be necessary to spray over the cloches more often. A mulch of compost is also very useful to help retain water.

It must be remembered that the glass of clo will need cleaning from time to time; the still needs the maximum light available, altho shading of certain crops may be necessary in sun.

Artichokes.—Two different plants are grow artichokes. One, the Jerusalem artichoke (*Hel thus tuberosus*), is related to the sunflower an grown for its tuberous roots, which are secon food value only to the potato. It will grow poor soil, but amply repays good cultivation, may be placed at the more exposed end of vegetable plot as a windbreak and screen. Tu should be planted during February or March well-manured ground in drills 4–6 in. deep, 2 ft. 6 in. apart, with 15 in. between the tub Hoe frequently during the summer and cut stalks down in early winter. The tubers may be lifted and stored, or better dug as requi reserving a number for replanting the follo February.

The other type, the globe artichoke (*Cy scolymus*), is often grown as an ornamental pl but is esteemed as a vegetable for its young, fl flower-heads, which must be cut before the sc begin to open, after which they become hard unpalatable. A deep, rich, well-manured so required, and after planting in early spring in 4 ft. apart, with 2 ft. between the plants, a c post or manure mulch is beneficial. A good may be expected for five or six years provide annual dressing of manure is applied. After time they should be replaced by young such

anted in a fresh position. A covering of straw bracken on the crowns is advisable during inter.

Asparagus.—This will grow on most types of il provided that drainage is good and that enty of organic matter is available. The site r the asparagus bed should be double dug in the utumn prior to planting, and a generous dressing about half a barrow load of manure per square rd incorporated. Crowns up to three years d may be bought, but it is found that one-year-d crowns give the best results. Plants may be btained cheaply by sowing seed in late March in rills 1½ in. deep and 18 in. apart and thinning e seedlings to 4 in. apart. It is thought that ale plants produce more stalks of better quality an female plants, but at present no supplies of ale crowns alone are available.

Planting may be on the single-row system or the ide-bed system. In the single-row system owns are planted 18 in. apart in rows 4½ ft. part; the wide-bed system consists of 5-ft. beds, ith three rows of crowns 15 in. apart each way, nd 2 ft. between each bed. Planting is best one during April and the plants are placed in a ench 8 in. deep and 1 ft. wide, with a slight dge at the base, and covered with 3 in. of soil. he remaining soil is worked in during the summer. he roots should never be allowed to dry out.

The following March 2 oz. per sq. yd. of sulphate ammonia should be applied; in subsequent ears 3 oz. per sq. yd. of "National Growmore" pplied at the same time, followed by 2 oz. per sq. d. of sulphate of ammonia in June, after cutting, n be used. Salt, as a fertiliser, is not recom-ended nowadays. An annual dressing of anure or compost in November is desirable.

No cutting should be done for the first two years ter planting and only a light cut taken in the ird year. After this a six-to-eight-week season ginning in early May is usual. The spears ould be cut when about 4 in. above soil level d severed about 2 or 3 in. below the soil, giving overall length of 6–7 in. The fronds should e cut in October before the seeds drop, but not uring the summer, as the plant is weakened. eeds should be kept down and in the autumn e plant may be earthed up.

Varieties: 'Connover's Colossal' and 'Kidner's edigree.'

Beans. Three types are commonly grown, as llows:

Broad Beans are the hardiest and can, in warm rdens, be sown during autumn to obtain an rly crop. Little is gained by this as a rule, and wing in well-manured ground in February, when e soil is frost free, with successional sowings uring March and April, is generally better in ost gardens. The soil is broken down, finely ked, and the seed sown 9 in. apart in drills 3 in. ep, with 18 in. between each row. If double ws are sown 10 in. should be left between the ws, and 2 ft. between each pair of rows. Stak-g may be necessary. Plants from sowings under ass or under cloches in January may be used to tain an earlier crop; the cloches should be moved in March and a further crop sown, and cloches.

Black aphis was a serious pest, but is now easily ecked by pinching out the young tips and apply-g malathion or lindane as soon as any are seen. e pods may be used before the beans are fully veloped and sliced as are runner beans, but rmally they are picked when the beans are well rmed but not tough.

Varieties: 'Aquadulce' and 'Green Master-ece.'

Dwarf Beans (which include French, Kidney, d Haricot Beans) may be either used as young ods in a similar manner to runner beans or eened in the pod for winter use. A rich well-anured soil gives the best results, and seeds wn during the first week in May, 2 in. deep and n. apart, in drills 18 in. apart, may be followed a second sowing at the end of May. The young nts should be thinned out to 1 ft. apart and all twigs used to stake them. If sown earlier, et damage may occur. Seeds may also be wn in the greenhouse and the seedlings trans-planted, or sown under cloches in the last week in March, provided the soil has been prewarmed.

The plants, as long as the pods are picked over frequently, will continue to bear until the frosts; a little liquid manure will be beneficial during the summer. A late sowing in July, cloched in September, will continue the season into the autumn.

If required for winter use (Haricot varieties) certain plants should be left unpicked and the pods allowed to ripen on the plants. They should not be picked green; if unripe when frosts come, the plants should be pulled up and dried in a shed.

Varieties: 'The Prince' (Cloche), 'Master-piece,' and 'Comtesse de Chambord' (Haricot).

Runner Beans are the most popular type, and can be grown in two ways: either without stakes, in which case the tips of main and side shoots are regularly pinched out to make a bushy, dwarf plant, a method often used by farmers, or staked, with cross poles, allowing the plants to climb to the tops of the poles before pinching. Seed is sown from early May (mid-April under cloches) until late June, depending on the danger of frost, usually in a double row with drills 15 in. apart, and with seeds 3 in. deep and 6 in. apart in the rows, alternate plants being removed later.

Staking should be done as soon as the first pair of leaves unfolds, and a surface mulch is then applied. If the beans are to be dwarfed the rows should be about 18 in. or 2 ft. apart, and pinching may be required about once a week. A good, well-manured soil is essential, and plenty of moisture is required. The flowers may fail to set in dry weather, and an evening spray of water is helpful in preventing this "running off." Harvesting should be carried out regularly while the pods are young, before the seeds swell; older pods are stringy and seldom worth eating.

Varieties: 'White Czar' (white-flowered, heavy cropper) and 'Streamline.'

Beetroot.—From mid-April onwards varieties of beet may be sown on soil that has not recently been manured but is in good heart; on freshly manured soils coarse, forked roots subject to crack-ing occur. If in poor condition a light dressing of a complete fertiliser should be given before sowing. Sow in drills 1 in. deep and 12 in. apart and make a first thinning to 4 in. apart when the first rough leaf appears, and a second later, leaving 9 in. between the plants. Transplanting is inadvisable. Early roots for summer pulling may be obtained from a sowing of a Globe type in mid-April, and the main sowing should be made during May or early June for the winter supply. A sowing under cloches in late February will provide roots for pulling in late May.

On a heavy soil the oval-rooted types are best, but on a lighter soil the long-rooted types may be used. A sowing in late July of the Globe type will provide beet for use at the end of winter. Salad beet from early sowings may be pulled as required; the main crop should be allowed to mature and is lifted in October before the roots become woody and tough. Any damaged roots should not be stored. Twist off the tops just above the roots, shake the soil from the roots, and store in boxes of sand or peat in a frost-free shed. If clamped outside, straw and a thick layer of soil should be used; if frost reaches them they are spoilt.

Varieties: globe—'Detroit Red,' 'Red Globe, and 'Crimson Globe'; oval—'Cobham Early'; long—'Cheltenham Green Top.'

Sugar beet is similar but is white, not red-fleshed, and is mainly a farm crop; if desired it may be grown in a similar manner. Care should be taken in hoeing all beet crops to avoid damage to the small surface roots which feed the swollen rootstock.

Borecole.—*See* Kale.

Brassica.—A generic name of vegetables usually known to gardeners as "greens." This group includes brussels sprouts, cabbages, cauliflowers, kale, turnips, kohl-rabi, broccoli, and couve tronchuda. As they are all related, similar soil and cultural treatment is needed, and many pests

and diseases are common to them. Each is dealt with under a separate heading.

Broccoli.—*See* **Cauliflower.**

Brussels Sprouts.—Young plants from seed sown thinly in a nursery seed bed during mid-March can be transplanted during May or June. The soil should be firm, well drained, in good heart, and contain adequate lime, some manure preferably having been dug in during the winter; a supplementary dressing of 2 oz. superphosphate and 1 oz. of sulphate of potash per square yard is given before planting. The young plants should be set out 3 ft. apart both ways, planted firmly, and watered in thoroughly. Regular hoeing is necessary, and about a month after planting a little soil should be drawn round the stems.

If growth seems weak a top dressing of nitro-chalk should be given and this repeated in early September. As the lower leaves yellow, cut them off and gather the sprouts as they mature, picking from the bottom of the stem. Where space is available a succession of sowings from March to June can be made to lengthen the cropping period.

Club root, the worst disease of brassicas, is kept in check by only using well-limed, well-drained soil, and dipping the roots in 4% calomel before planting, and cabbage root fly, a frequent insect pest, by using dieldrin.

Varieties: early—'Cambridge No. 1'; mid-season—'Rous Lench' and 'Triumph' (dark foliage, distinct).

Cabbage.—Sowings in March and April for summer use, in May or June for winter use, and in late July or August for spring use will give a succession of cabbages all the year round. Seed is sown thinly in a nursery bed of well-firmed, limed soil, clear of weeds, in drills ½ in. deep and 6 in. apart, and the seedlings are dusted with D.D.T. to check flea beetle attack (prevalent with all brassica seedlings). All cabbages are gross feeders, and a well-drained soil in good heart, with adequate lime, is required.

"Spring cabbage" should be sown during late July (north) and August (south). If sown too early the plants may "bolt" without making a heart. The young plants are set out in mid-September 18 in. apart and with 18 in. between the rows if for hearting, or 9 in. apart with 18 in. between the rows, in which case the alternate plants are cut for "spring greens." On a heavy soil ridging along the rows of plants keeps the soil round the roots drained and helps to prevent loosening by frosts. In cold districts cloches may be used with advantage to help plants through the winter. In early March a dressing of 1 oz. per sq. yd. of sulphate of ammonia or nitro-chalk is a good stimuiant.

Seed of "summer" and "autumn cabbage" is sown in March and April and planted during late May and June, 18 in. to 2 ft. each way between the plants, depending on the variety. The plants should be thoroughly watered, both before and after transplanting. A top dressing of 1 oz. per sq. yd. nitro-chalk may be given if required.

"Winter cabbage," maturing from October to February from sowings during May and early June, are set out 2 ft. apart each way in July or early August, usually on ground which has been cropped with early potatoes or peas. No nitrogen fertiliser should be given late in the season, as soft growth, liable to frost damage, is encouraged. A balanced fertiliser, such as "National Growmore," may be used if needed. When the stalks of cabbage are left standing over winter a common practice is to cut across the tops to obtain bunches of leaves, for use as greens during early spring.

"Savoy cabbages" mature during winter and early spring from seed sown in May. Seedlings are transplanted in late July and early August on to land manured for the previous crop, to which a dressing of 2 oz. superphosphate and 1 oz. sulphate of potash per square yard has been given. The young plants should be set out 2 ft. apart each way; they are exceptionally hardy, and should be grown in every garden in case of a hard winter.

Varieties: Spring sowing—autumn cutting, 'Greyhound' (early), 'Winningstradt.' Autumn sowing—spring cutting, 'April,' 'Wheeler's Imperial,' Savoy 'Ormskirk Late Green.'

Red Cabbage is slow to mature; plants from sowings in August are transplanted 6 in. each way in autumn and set out in early spring 18 in. each way. They are ready to cut in late summer.

Cardoon (Cynara cardunculus).—Closely related to the globe artichoke and grown for the blanched hearts. Seed is sown in trenches 18 in. wide and 1 ft. deep; 8 in. of manure is worked into the bottom soil and covered with 3 in. of fine soil. Three or four seeds are dibbled in every 18 in. and covered with a flower pot till visible, and the thinned out, leaving one strong seedling at each station. Protection from sun and late frosts is provided by twigs over the trench, and copious watering is given during the summer. On a dry day in September the plants are blanched by tying the leaves together and covering with straw, hay, 3 in. thick, kept in position by raffia, or earthed up in the same way as celery. Blanching is completed in about a month. Litter over the top protects them from frost.

Carrots.—A light, well-drained soil, enriched with decayed organic matter, is suitable for carrots. No fresh manure should be given, but a light dressing of "National Growmore" fertiliser can be applied prior to sowing. The surface is left rough until sowing time and then broken down to a fine tilth. The first sowing is made in early April in drills ½ in. deep and 12 in. apart, and a succession is obtained by sowing at intervals of a month until the end of July.

On heavy, unfavourable soils stump-rooted varieties are best grown, long-rooted varieties needing a light soil. Thin out the stump-rooted varieties to 4 in. apart and the longer varieties to 6 in. Thinnings should be removed and the soil pressed firmly back to minimise damage by carrot fly. The early sowings are pulled as required, but the later sowings for winter use should be lifted in October and stored in slightly damp sand in a frost-proof shed or clamped in the open.

Frames and cloches are sometimes used to obtain early and late carrots. Seed of a quick-growing variety, such as 'Amsterdam Forcing' or 'Early Nantes,' sown in late January under cloches or frames will provide an early crop; the same varieties sown in frames or cloches in early August will provide young carrots for the autumn. Carrot fly is a bad pest, especially on light soils; the seedlings should be dusted with lindane or dieldrin when 2–4 in. high to prevent the flies from egg laying.

Varieties: globular—'Early Gem'; stump-rooted—'French Short Horn'; intermediate—'Amsterdam Forcing' and 'Early Nantes'; long—'St. Valery' and 'Long Red Surrey.'

Catch Crops.—A term used for quick-growing crops interplanted between rows of other crops. Radishes between rows of broad beans, lettuce between celery rows provide examples. In this way the best use of a limited amount of land can be made.

Cauliflower.—Broccoli is for all practical purposes a hardy winter cauliflower. Seed is sown ½ in. deep in a nursery bed from mid-April to mid-May, depending on the variety, and the plants planted during June and July on to firm soil, manured for the previous crop. The plants are set out 2 ft. apart each way; 2 oz. superphosphate and ½ oz. of sulphate of potash per square yard may be hoed in before transplanting. A nitrogenous manure should be given late in the year.

Varieties: cauliflower—'Snowball' (summer), 'Majestic' (autumn). Broccoli—'Snow's White' (winter), 'St. George' (early sprouting broccoli—'Nine Star Perennial' (the many-headed sort).

Sprouting broccoli is very hardy, has a non-leafy head, and is cultivated in the same way. Purple- and green-sprouting varieties are grown.

Summer cauliflowers require a soil which has been limed and manured during the winter; 2 oz. per sq. yd. of superphosphate should be given before transplanting. An early sowing in fra

n February or March will provide plants for cropping in June. These should be hardened off and planted in March or April from 18 to 24 in. square, depending on the variety. Seed sown outdoors in April in drills ½ in. deep will give plants for transplanting in May or June, for cropping from late July onwards. If growth is slow a dressing of 1 oz. per sq. yd. of sulphate of ammonia should be given. Leaves broken over the curds will help to prevent any damage from early frosts. Varieties given in previous paragraph.

Celeriac.—A plant allied to celery grown for its edible root, which resembles a turnip but has the flavour of celery; the stems are bitter to the taste and are not eaten. It is used in salads or boiled as other root crops. Seed is sown in gentle heat in March and seedlings pricked out into seed-boxes, 2 in. apart each way. In June, after hardening off, the seedlings are planted out in shallow drills 18 in. apart, leaving 12 in. between each plant in the row. Water freely during the summer and remove side shoots as they appear. Lift the roots in October or November and store in a frost-free shed.

Celery.—Richly prepared ground is required. A trench 15 in. wide and 1 ft. deep is taken out and manure worked into the bottom of the trench. The soil is then returned to within 3 in. of the ground level. Seed should be sown in early March at about 60° Fahrenheit and the seedlings pricked out in deep boxes 3 in. each way and gradually hardened off. Celery seed is very fine, and care should be taken to cover it with only a fine layer of soil; if covered too deeply it may not germinate.

In late May or June set the plants out in staggered double rows 1 ft. apart, with 10 in. between the plants, and water them in. Frequent watering during the summer is required, and a light dressing of nitrate of soda will stimulate them if growth is poor. Before earthing up to blanch the plants, tie the stems loosely below the leaves and remove any suckers. Earthing up begins when the plants are about 15 in. high; the ground should be moist, and the first earthing should only be slight. The second and third earthings, at intervals of about three weeks, should be more generous, but should never reach higher than the base of the leaves, and no earth should fall into the heart. For exhibition purposes brown-paper collars may be tied round the stalks before earthing. The final earthing should cover all the stems right up to the leaves, and the soil should slope away neatly. In winter litter or bracken spread over the plants will help protect them from frost.

Celery fly is a serious pest, and the brown leaf-blisters should be pinched to kill the maggot inside, and lindane applied two or three times at fortnightly intervals. Slugs should be discouraged with a good slug killer. Leaf spot, a seed-borne disease, can be prevented by spraying with Bordeaux mixture.

Varieties: white—'Solid White'; pink—'Clay Worth Prize Pink'; red—'Standard Bearer'; self-blanching—'Golden Self-Blanching.'

Chervil.—An annual herb sown during March in drills 10 in. apart, and thinned to 6 in. in the rows. Further sowings can be made during the summer. Used in salads and soups.

Chicory.—The young, blanched growths are used in winter salads. Seeds are sown in drills 1 ft. apart in May; the young seedlings are thinned to 8 in. apart and grown on until October or November, when they are lifted and the roots trimmed to 8 or 10 in. long. They are then planted in deep boxes in a moist, sandy soil 5 in. apart each way, leaving 1 in. above the soil surface, and the boxes put in a warm greenhouse or cellar. No light must reach the crowns; one method sometimes used is to cover the crowns with 6 in. of sand. When the blanched growths show through they are about 6 in. high and ready for cutting.

Chives.—These are like small onions, and the leaves are used for flavouring salads and soups. They are easily grown in window boxes and town gardens. Bulbs can be planted in March 6 in. apart, and divided when the clusters become too large.

Corn Salad or Lamb's Lettuce.—Occasionally grown for the leaves, which are used in early spring salads. Seed sown from August to October will provide plants for winter and spring use.

Couve Tronchuda.—A large brassica known as "Portugal cabbage," not generally suitable for smaller gardens. Seed is sown in March and the plants set out 2–3 ft. apart each way. The hearts may be cooked in the same way as cabbage.

Cress.—An annual growing rapidly from seed and used as a salad when only the seed leaves have developed. Seed sown as required, in boxes of light, moist soil and covered with brown paper until germination, when it is removed, will provide salad all the year round. The seed is merely pressed into the soil and the boxes kept moist. Cress may even be grown on damp flannel in a window.

Cucumber.—The cucumber of the shops is grown as a specialist crop under glass. Temperatures of 85° Fahrenheit or more may be required, and only occasionally are they grown by the amateur, although cloche and frame culture is now popular.

Ridge cucumbers, which are smaller and prickly outside, may be grown outdoors in summer. Plants from seed sown singly in pots under glass can be planted during late May on ridges of good, well-manured soil or, alternatively, sown on the ridges 1 in. deep at the same date. Water freely during the summer and cut the cucumbers while young to encourage further production.

If cloches are available greenhouse-raised cucumbers can be planted under them, in mid-April. Frame cucumbers are less hardy, but young plants raised under glass can be planted under cloches in early May.

Varieties: ridge—'King of the Ridge' and 'Stockwood Ridge'; frame—'Conqueror' and 'Telegraph.'

Endive.—Used in winter or autumn salads. Seed is sown during April in drills 18 in. apart and the seedlings thinned to 12–15 in. apart. Sowings in June and August will provide a succession. A rich soil and plenty of moisture are the main requirements; before eating blanching is necessary, as the leaves are very bitter. This is achieved by tieing the leaves loosely together and covering the plants with inverted flower pots (with the holes blocked) to exclude the light; frost should be kept out by piling litter over the pots in winter. If cloches are used they can be coated inside with lime-wash to achieve the same effect. Alternatively, plants may be lifted in October and blanched in darkened frames.

Varieties: summer—'Green Curled'; winter—'Batavian Broad Leaved.'

Fennel.—A perennial culinary herb used in fish sauces and salads. Blanched stems may also be cooked in the same way as celery. Seed is sown in drills 2 ft. apart in rich soil and the seedlings thinned to 18 in.

French Beans.—*See* Dwarf Beans.

Garlic.—One or two "cloves" planted in February, 9 in. apart, will provide ample garlic for salads, as only a little is required. After growth is complete in summer the bulbs can be lifted, dried, and stored and some saved for replanting.

Haricot Beans.—*See* Dwarf Beans.

Herbs.—Many herbs are useful in small quantities for flavouring and garnishing, as well as being decorative. If possible, a separate herb garden should be made as a feature in the garden, or they

may be used as edging plants. Perennial herbs, of which borage, caraway, chamomile, chives, fennel, garlic, horseradish, lavender, mint, penny-royal, marjoram, rosemary, rue, sage, tansy, tarragon, and thymes are the main types grown, should be given a permanent position. Those grown as annuals—anise, basil, coriander, dill, parsley, purslane, and summer savory—can be used as "fill-ins" on the vegetable garden. Brick and cobble paths associate well with herbs, imparting something of the character of the gardens of bygone days, when herb gardens were considered one of the most important features.

Horseradish.—A deep-rooting perennial herb which appreciates a well-manured, moist soil. It is easily propagated from root cuttings and can become a nuisance, as pieces of root left in the soil will make a new plant; care should be taken to lift the complete root when digging it for use. Straight roots planted in spring with the crowns 6 in. below soil level and 1 ft. apart can be lifted for use in autumn; no further treatment is required, apart from keeping weeds in check. Some of the roots should be kept for planting the following spring.

Kale.—Very useful during a cold winter, when other green vegetables are scarce, because of its hardiness. Seed sown in April or May will provide young plants for transplanting 18 in. apart each way in July or early August, on to a site used for peas or early potatoes, in good heart. A catch crop of lettuce can usually be taken from between the rows. The variety 'Hungry Gap' is usually sown in rows 18 in. apart where it is to mature and thinned, leaving 18 in. between the plants. There are many varieties; which types are grown is a matter of personal preference.

Varieties: 'Cottager's' and 'Hungry Gap.'

Kidney Beans.—*See* Dwarf Beans.

Kohl Rabi.—A brassica with a swollen stem base, in flavour and appearance something between a turnip and a cabbage. Seeds sown in April in rows 1 ft. apart are thinned to 1 ft. apart in the rows, and the swollen stem harvested when about the size of a tennis ball. If left to grow it becomes coarse.

Lamb's Lettuce.—*See* Corn Salad.

Leeks.—A vegetable which repays planting on a well-manured soil. If they are to follow winter greens, then manure or compost should be dug in after the previous crop is cleared. Leeks may be sown from early March to April in lines 8 in. apart on a prepared seed bed, and the seedlings transplanted as land becomes available during June and July, when about 6 in. high. Thinning in the seed bed should be unnecessary provided the sowing has been correct. The seedlings are set out 9 in. apart in rows 15 in. apart; a hole is made with a dibber, and each seedling dropped in and watered thoroughly. No firming is needed, the watering should tighten the plants sufficiently. Alternatively, drills 4 in. deep and 15 in. apart can be drawn out with a hoe and the plants put in 9 in. apart in the drills.

Regular hoeing is required, and a feed of sulphate of ammonia (1 oz. per gallon of water) can be applied if in poor growth. In September a little earth should be drawn up around the roots, which should, by then, be almost full grown. Leeks are very hardy and can be left in the soil until required for use.

Varieties: 'Lyon' and 'Musselburgh.'

Lettuce.—Two main types are grown: cos lettuce, a summer crop with long, straight leaves that curl inwards naturally or are tied in so that the heart is more or less blanched; and cabbage lettuce, which are broad and spreading, with round cabbage-like hearts, and are grown to supply salad all the year round. Lettuce should be grown on ground manured during autumn or winter, dug and left rough till planting time, when it is broken down and raked to a fine tilth. Seed, sown in January in frames and cloches outdoors in March and at fortnightly intervals thereafter, a little at a time, until September outdoors, or October in frames and cloches will provide lettuce for most of the year. Sow thinly in drills ½ in. deep, in rows 1 ft. apart, and thin out or transplant young seedlings so that they are 9–12 in. apart, depending on the variety. Quick unchecked growth with adequate moisture is required; a dressing of bonemeal worked into the soil before planting and a light dressing of sulphate of ammonia in water on poor soils will help growth considerably. Aphids may be troublesome, and should be checked by using lindane or malathion.

Varieties: summer—'All the Year Round' and 'Continuity'; early spring—'Arctic King' and 'Cobham Green.'

Maize.—*See* Sweet Corn.

Marrows.—Pumpkins, gourds, bush, and trailing marrows all require similar treatment; plenty of sun and water and a rich soil, such as an old bonfire bed or compost heap, which will provide a porous medium of humus. Seed can be sown singly in pots under glass in March, or outdoors on the site in May. For cloches a bush variety must be used, and greenhouse-raised plants are cloched in mid-April. Plant four or five seeds in groups about 6 in. apart and 1 in. deep and finally thin to the strongest plants 15 in. apart. Protection from late frosts may be necessary. Water copiously and regularly. Cut marrows when about 12 in. long to encourage further fruits. Some can be left until they are full size and cut before the frost for storing in a dry, frost-proof place.

Varieties: bush—'Green Bush' and 'White Bush'; trailing—'Long Green Trailing.'

Melons.—Although usually a glasshouse crop, melons can be grown outdoors under cloches or in frames. Seed is sown under glass in April at 60° Fahrenheit, and seedlings can be set out 2 ft. apart in early May. The soil should be manured generously and the seedlings planted on a mound of compost mixed with soil. The plants must be stopped at the fourth or fifth leaf to encourage laterals. Two can be selected to grow on singly when 18 in. long, pinched out to obtain side laterals, which will bear the fruit. The female flowers may require pollinating, and on a sunny day a male flower or rabbit's tail can be used to transfer the pollen; as soon as the young fruits swell, remove all but two or three per plant and pinch back the laterals bearing fruit to two leaves from the melon. A feed of dried blood once a week with plenty of watering (though not saturation) will help the developing fruits. Light shade may be necessary.

Varieties: 'Dutch Net' and 'Tiger.'

Mint.—Easily grown from suckers in any soil. For winter use a few pieces can be planted in a frame. A number of varieties—'Apple Mint,' 'Peppermint,' and 'Spearmint'—can be grown besides common mint.

Mushrooms.—Growing mushrooms is really a specialist occupation. For the experimenting amateur, beds of composted stable-manure can be made up in a warm, damp cellar or disused air-shelter. Pieces of spawn are inserted when the temperature of the compost has dropped to about 70° Fahrenheit and the whole bed covered with an inch of inert sub-soil. The air temperature should be from 60° to 70° Fahrenheit, and a few weeks mushrooms may appear. Full instructions will be given with the spawn, but it is advisable to consult a text-book dealing with the culture, as even for professional growers a crop is never certain.

Mustard.—Grown exactly in the same way as cress, but is ready two or three days earlier. If used together, mustard seed should be sown two or three days after cress. Again it is the young leaves which are eaten.

Onions.—These respond well to good cultivation. The site is dug deeply in winter, manu

corporated, and left rough until February, when is broken down to a fine tilth and firmed well. eed can be sown ¾ in. deep in drills during ugust and planted in March for exhibition onions. t the usual practice is to sow seed in late Feb- ary outdoors or under glass in January and anspiant during April in rows 12 in. apart with in. between the onions, taking care to keep the ses about ½ in. below the surface. If sown tdoors and thinned the thinnings may be used salads. Autumn-sown onions are liable to bolt, t less liable to attack by onion fly than spring- wn plants.

Dressings of sulphate of ammonia or nitrate potash may be given during the growing season, t not later than July. In August the tops are nt over to hasten ripening and the bulbs har- sted in a dry spell at the end of the month, st laying them on the ground for a day or o to dry off. They should be stored in a dry, ry place. The chief pest is onion fly, controlled dusting the seedlings with aldrin at the loop nge. Onion sets are small onions produced e previous summer, stored and replanted in ring to obtain very large bulbs. They are rticularly valuable on poor soils.

Varieties: spring sowing—' Bedfordshire Cham- on,' ' Best of All,' and ' White Silverskin ' ickling); autumn sowing—' Giant Zittau,' Sutton's Solidity,' and ' White Lisbon ' (salad ions); sets—' Ebenezer ' and ' Stuttgarter eisen.'

Parsley.—Sow thinly in rows 8 in. apart during arch and again in July for a succession of young liage; thin to 4 in. between plants.

Parsnip.—Grow parsnips on ground manured r a previous crop; if given fresh manure split- ng and forked roots occur. Dig the soil deeply, d at sowing time in March, work the soil to a ne tilth. On a soil unsuitable for deep-rooted ops special holes 10–12 in. apart, filled with fted soil, may be prepared. If this method has be used four or five seeds are sown per hole; ormally drills 15 in. apart and 1 in. deep are made d four or five seeds sown every 9 in. The seed- ngs are thinned, leaving one at each station. arsnips should be left in the ground until needed; ter over the rows will ease lifting in frosty eather.

Varieties: ' Evesham ' and ' Student.'

Peas.—Dig the ground well in autumn and add generous amount of manure or compost. Seed owing begins at the end of February, and can be ntinued at three-weekly intervals until early ly. Under cloches sowings in January and ctober will lengthen the season. Both early d late sowings should be of a quick-maturing ariety. Seed is sown in drills 6–8 in. wide and in. deep, with 2 ft. between drills; the seeds can e scattered thinly in the drill or spaced 3 in. part in a treble row. Cover with 2 or 3 in. of oil and as soon as the peas are about 2 in. high ake with twigs.

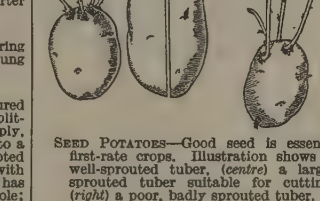
Failures are often due to attacks by birds and eld-mice. The former should be discouraged y netting and the latter by trapping. Pea-sticks ill be necessary for the taller varieties which hould have 3–4 ft. between the rows. With nited space only the dwarf quick-maturing arieties should be used. A summer mulch will eep the soil moist, and picking should be done egularly.

Varieties: 1½–2 ft.—' Kelvedon Wonder,' Kelvedon Triumph,' and ' Meteor ' (cloches); ft.—' Onward '; 3½–4 ft.—' Gladstone.'

Potatoes.—In general, it is only economic for he amateur to produce an early crop; the main inter supply can be grown if room and labour are vailable. They should be grown on land well nanured the previous season, dressed at planting me with a mixed fertiliser, such as " National rowmore," at a rate of 1½ lb. to a 30-yd. row. he soil should not contain too much lime, as the amage of scab disease is increased.

" Seed " tubers about the size of a large egg are est used, and these can be bought or saved from he previous season's crop. Large potatoes may be cut leaving about three eyes to each part. New stocks should be bought occasionally if the " seed " is home saved to obviate risk of virus. " Seed " should be put in trays during February in a frost-proof shed to sprout, and in early April the " first-earlies " can be planted.

Drills 2 ft. apart and 4–5 in. deep are taken out and the sprouting " seed " planted 12 in. apart in the rows. Maincrop varieties are planted in early May 15 in. apart. The young growths should be protected from frost by earthing up slightly, and a further earthing is done as the potatoes mature. This practice of earthing prevents the tubers near the surface from becoming green when exposed to light, keeps weeds down, and protects the tubers from spores of potato blight, which are washed into the gullies. If growth is poor sulphate of ammonia can be applied at a rate of ½ lb. per 30-yd. row. Early varieties should mature in late July and later varieties in September and October; when the tops (haulm) turn yellow the crop can be lifted, dried for a few hours (too much light will turn them green), and stored in boxes in a frost-proof shed or clamps.



SEED POTATOES—Good seed is essential for first-rate crops. Illustration shows (*left*) a well-sprouted tuber, (*centre*) a large well-sprouted tuber suitable for cutting, and (*right*) a poor, badly sprouted tuber.

Potato blight is a common disease, and control by spraying with " Bouisol " before the leaves touch in the rows is effective. Virus diseases, spread by greenfly, are checked by using " seed " from Scotland, where greenfly is less troublesome because of the lower temperatures. Colorado beetle should be watched for, and if found notified to the Ministry of Agriculture.

Varieties: Discerning growers will find the following well worth growing: ' Edzell Blue ' (violet-coloured skin; excellent cooker), ' Pentland Dell ' (white-fleshed; heavy cropper), ' Red Craigs Royal ' (red-fleshed; heavy cropper), ' Ulster Chieftain ' (white-fleshed, good early variety). Epicureans seeking a first-class potato should grow ' Maris Peer ', a sort understandably gaining in popularity in Scotland, since its introduction. Another interesting sort is the Dutch-raised ' Record ', a yellow-fleshed variety which has a trace of sweetness in its flavour.

Pumpkin.—*See* Melon.

Radish.—Most cultivated ground is suitable for growing radishes; successional sowings at fortnightly intervals from early March until May in drills ½ in. deep should be made. Summer-sown radishes bolt and are hot and tough, but autumn sowings for late salads can be made. As radishes germinate very quickly, they can be sown together with another crop and used quickly, and also enable the rows to be seen and hoed early.

Varieties: ' French Breakfast ' and ' Scarlet Globe.'

Rhubarb.—Before planting the ground should be generously manured and deeply dug. Crowns are planted in March, 3–4 ft. apart each way and mulched, but no rhubarb should be pulled until the following year, when a light pull can be taken. Remove any flowering shoots and give a dressing of sulphate of ammonia if growth is weak. Manure well each winter; if early supplies are needed, some of the crowns can be covered with inverted boxes or barrels and a packing of loose straw or bracken. An established, well-cultivated bed will continue almost indefinitely.

Sage.—A hardy shrub for the herb garden easily raised from cuttings. The leaves are harvested and dried in summer.

Salsify (Oyster Plant).—A winter root rather like a parsnip which requires similar growing conditions.

Savoy.—*See* Cabbage.

Scorzonera.—A winter root cultivated in the same way as salsify. It has a purplish root instead of the yellow-green one of salsify.

Sea-kale.—A perennial plant native to our seashores, which can be either grown from seed sown in March and left for two years to produce forcing crowns or from bought thongs, which are planted during March, 9 in. apart in groups of three, leaving 3 ft. between groups. During summer a manure mulch and nitrogenous fertiliser can be applied. When the tops die down in autumn the crowns are covered with boxes to force and blanch the new growths. Crowns can be covered in succession to keep a supply. Earlier sea-kale can be obtained by lifting crowns in November. These are planted in batches five or six to a pot, watered well, and a second pot, with the hole blocked, placed over them. In a warm greenhouse or similar position they should develop sufficiently for cutting in about three weeks. Slugs are the chief pest outside, and should be kept in check by a proprietary slug-killer.

Shallots.—A popular crop for the small garden. Shallots are purchased as bulbs, like small onions. A deep, well-manured soil is required, as for onions, and they are planted during February, the bulbs being pressed about half their length into soft soil, 6 in. apart in the rows, leaving 1 ft. between rows. In mid-July the little bunches of bulbs can be lifted. Leave them on the surface to dry for a few days and then store in a dry, frost-proof shed. Some, about the size of a shilling, should be kept for planting the following year.

Spinach.—Sowings in February to April on a well-manured soil will provide a succession during the summer. Sow in drills 1 in. deep and 12 in. apart and thin the young plants to 3 in., and then to 6 in., using the second thinning to eat. A sowing of the prickly variety in August at the same distances will provide a winter crop. When picking gather a few leaves from each plant in the row.

Varieties: 'America ' and ' Giant Prickly.'

Sprouting Broccoli.—*See* Cauliflower.

Sugar Beet.—*See* Beetroot.

Swede.—*See* Turnip.

Sweet Corn (Maize).—Gardeners should distinguish between the types of maize used for poultry food and those which supply sweet corn for human consumption. It is wise to use cloches for growing sweet corn, as it is only half-hardy and resents transplanting. Seeds sown under cloches in mid-April in two drills 12 in. apart and 1½ in. deep should be placed 1 ft. apart in staggered positions in the rows. More robust varieties may need 15 in. from plant to plant. A soil well manured for the previous crop is best used, and a mulch can be given as soon as the plants are a few inches high. The first cobs should be ready by mid-July, and should be eaten when the cob is milky.

Variety recommended: ' John Innes Hybrid.'

Tarragon.—A herb used for flavouring vinegar. Raised by root division in spring. Cut down and dried for use in winter.

Tomato.—A sunny, sheltered site is required, otherwise ripening outdoors in our climate is uncertain. Sow seeds under glass in late March and harden off the plants in a cold frame or buy pla for setting out in late May or early June. soil should be thoroughly dug and some artifi manure applied before planting. Allow 18 between plants and 2½ ft. between rows, and in a strong stake with each plant. Keep t single stem, pinching out side shoots regula When four or five trusses are set pinch out top of the main shoot.

Feed with a liquid manure during summ Fruit which fails to ripen outdoors can be gathe and stored at about 50° Fahrenheit or the pla laid flat on the ground and covered with cloc when the tomatoes should ripen. Under cloc plants can be planted out in mid-April instea late May, gaining six weeks growing time, and Cloches removed when they become too large.

Potato blight attacks tomatoes, and a spra " Bouisol " during the first week in August repeated after fourteen days will give a contro

Varieties: ' Market King ' and ' Mon maker '; some heavy-cropping sorts have li or no flavour and a thick skin.

Turnips.—Ground manured the previous sea should be dug well and dressed with 2 oz. su phosphate per square yard. An early var can be sown during April in drills ½ in. deep 15 in. apart, followed by successional sowing three-week intervals as required. The main c for storage is sown in July and August, and se lings should be thinned gradually to 10 in. ap Use when about the size of tennis balls. A sow can be made in September, left almost unthin and the tops used as " greens " in spring. autumn the storage crop is lifted and all damaged roots put in sand in a shed or clamp Flea beetle and turnip fly can be checked D.D.T. at the seedling stage.

Swedes are grown in a similar manner.

Varieties: turnips—' Early Milan ' (summ and ' Green Top Stone ' (winter stora swedes—' Purple Top.'

FERTILISERS AND ORGANIC MANURES

The elements essential for healthy plant gro may be roughly grouped into classes—first, t required in some quantity, the major eleme nitrogen, potassium, and phosphorus; secon calcium, magnesium, and sulphur, which required in lesser quantities; and thirdly, trace elements, boron, manganese, iron, z copper, and molybdenum, of which only mi quantities are needed. As well as the eleme mentioned, others, such as silicon, alumini chlorine, nickel, and sodium, are often found plant analysis, but the evidence that these essential is inconclusive, though they may beneficial to certain crops.

It is important to remember, when ad fertilisers to the soil, that different crops require relatively more of one element t another, but a balance between all the elemen essential. As an instance, brassicas (the cabb family) are gross nitrogen feeders, while root c (*e.g.*, carrots) require far less nitrogen, and excess may be harmful. A further point to no is that although an element may be present in soil the plant may be unable to absorb any beca it is being kept in an insoluble state by exces another element. An instance of this is the quent yellow and sickly appearance of plants very chalky soils due to lack of iron, whic present, but locked in an insoluble state by much calcium.

The elements needed by the plant are in form of various compounds, such as nitrates phosphates, and may be applied as artifi fertilisers, which are manufactured, or as hum which contains most of the foods required

lso provides the essential soil micro-organisms r bacteria, without which the soil would be inert nd no plants would grow. Bacteria break down ne complicated animal and vegetable matter of hich humus is composed to soluble compounds hich plants can absorb. Humus can be supplied s farmyard and poultry manure, leaf mould, ompost, sewage sludge, spent hops, and from nimal by-products like hoof and horn, dried lood, meat and bone meal, and many others.

Nitrogen is mainly concerned with vegetative rowth, encouraging leaf and stem formation. It also contained in chlorophyll, the green colouring matter of the plant, and one of the symptoms f nitrogen starvation is a pale-green colour to the af, indicating a lack of chlorophyll. Most of ne nitrogen compounds used are soluble, and it is wise maxim to apply "little and often"; if ven in large doses much is washed through the il and wasted.

Nitrogenous fertiliser should not be given to any ant late in the season, as sappy growth, easily amaged by winter cold and frosts, is encouraged. milarly, at no time should large quantities be iven to any plant, as this results in an excess of afy growth, which is very susceptible to disease nd adverse conditions of drought and cold; also ants tend to be later flowering.

Sulphate of ammonia is the most used inorganic trogenous fertiliser, and is excellent for spring se on seed beds, lawns, and early crops, and it is ntained in most fertiliser mixtures. It makes ils acid in reaction, and if both lime and nitrogen e required, nitro-chalk should be used instead. ther nitrogen fertilisers used are potassium trate, which has the advantage of supplying two ajor elements at once, and is very soluble, and trate of soda, often used on beet and mangolds. he latter chemical should not be applied in ccess, as too much sodium has a bad effect on il structure. These inorganic fertilisers are all luble and quick acting. As a general guide, 1 oz. the fertiliser to a gallon of water, applied at oz. to a square yard, is a good general summer ressing, given at intervals of two or three weeks. should always be given after rain or watering, nd should be applied to the soil and not to the liage.

Among organic fertilisers containing a perntage of easily available nitrogen are dried ood, soot, and meat and fish meals. Slower to compose, and so having a more lasting effect, e shoddy (wool waste) and hoof and horn.

Phosphorus is concerned in the plant with the oduction of young cells of the root and shoot, nd also encourages flower and fruit production nd early ripening. Most of the compounds are latively insoluble (rendering absorption by the ant difficult), and so large amounts can be supied without deleterious effects, especially on acid ils, where the availability is less than on alkaline ils.

Phosphorus is generally applied to the soil in e form of phosphates, and among these superosphate of lime is quick acting, and is usually pplied at 2–3 oz. per sq. yd. in spring and sumer, when the need is greatest. More slow acting basic slag, a by-product of the steel industry, nd as a fine black powder and containing, besides osphates, many of the trace elements, as well a considerable percentage of lime. This is od for application to acid, wet soils, but should t be applied to potatoes owing to the risk of ab disease with the increase in the content of ne. It should not be applied with sulphate of mmonia. Bonemeal is also slow acting and also ntains some nitrogen. It is excellent for crops e tomatoes, and is also used extensively for namental and pot plants.

Potassium, the third major element, is essential r good flower colour and ripeness in fruits, ssert apples, potatoes, cereals, and root crops need potash in some quantity, and if excess trogen has been applied a dressing of potash may unterbalance the effect. Sulphate of potash is e main inorganic compound in use. Muriate potash (potassium chloride), to which some ops are sensitive, is much less used; it should be applied as a winter dressing before the crop is sown to lose the impurities by weathering. Sulphate of potash is purer, and may be applied during the growing season at 1 oz. per sq. yd. on the vegetable plot, and is used in many proprietary fertiliser mixtures.

Wood ash contains variable quantities of potassium, and provided that the ash has not been washed by rain and the potassium leached out, is a useful addition to the soil; bracken, cut during June and July, when large amounts of potassium are present in the foliage, can be composted when green to provide a good supply of the element.

Elements Required in Lesser Quantity.—Calcium, although required in small quantities in the plant, has profound effects on the soil. Its main function in the plant is in the production of the cell walls, but in the soil it helps to bind light soils together and to make the structure of sticky clay soils finer and more workable. Also soils without calcium are acid and tend to lock up some elements in an insoluble form. Addition of calcium changes the acidity, making it slightly alkaline or neutral, and releases the locked elements.

Calcium is applied as some form or derivative of calcium carbonate, commonly known as lime, which can be obtained in various forms. Hydrated or slaked lime (calcium hydroxide) is commonly used on clay soils, and chalk or ground limestone on lighter soils. Calcium is gradually leached from the soil, and it is necessary to replace it, or the soil becomes too acid and many crops will fail to grow. A normal dressing of lime for a vegetable garden is about 4 oz. lime or ½ lb. chalk per square yard every two or three years, and is best applied in autumn as a surface dressing after digging. It should not be applied together with other fertilisers. The amount of lime will depend on the type of soil, but it must be remembered that most vegetables grow best on a slightly acid soil.

Gypsum, or calcium sulphate, is sometimes recommended to supply calcium, but its solubility is negligible, and it is preferable to chalk or limestone only on soils containing salt due to sea flooding. It has been used to help reclaim parts of East Anglia flooded by sea-water during the storm surge of January 1953 by improving the soil structure. Sulphur, as sulphates, and magnesium, as an impurity in limestone, are usually present in sufficient quantities for the plants' needs.

Trace Elements.—In the case of the trace elements most soils contain enough for the plant, but in certain circumstances deficiencies occur. Iron on very alkaline soils is insoluble and, as it is essential for the production of chlorophyll, deficiency results in the chlorosis of the leaves. It can be rectified by spraying the leaves with "Sequestrene Plus," as can the lack of magnesium and manganese, which may also be deficient on acid soils.

Chlorosis in brassicas and marsh spot of peas are due to magnesium deficiency. Boron deficiency, often occurring on light, calcareous soils, is responsible for brown heart of cauliflower and several other "diseases," mainly affecting the growing point. It can be rectified by applying borax to the soil at about 1 oz. per 15 sq. yd. Zinc and copper deficiencies are unusual in England, but lack of molybdenum has caused whiptail disease of cauliflower. Only minute quantities of the last three are required; more may be poisonous to plants and animals.

Organic Manures.—It should be noted that most of the deficiencies will not concern the amateur, especially if he keeps the ground in good heart with ample organic manure, which contains all the plant foods necessary. Well-rotted farmyard manure from cows and pigs is by far the best organic food, but is scarce now, good farmers returning it to their own land, and generally the material offered is low in nutrients. Poultry manure, which is rich in soluble nitrogen salts, is excellent either applied direct to the soil (not to the growing crop for fear of damage) or composted with straw.

Many substitutes have been devised to use in place of manure, among them sewage sludge, best applied some time before growing the crop, spent hops from breweries, dried seaweed, excellent for potatoes when supplemented by superphosphate, soot, rich in nitrogen, composted town refuse, and the waste organic animal products mentioned earlier. The organic matter in all these materials is essential for maintaining the soil structure and cannot be replaced simply by artificial fertilisers.

Liquid manure, produced by suspending an old sack of animal manure or soot in water for a few days, is useful for the amateur to apply to pot plants and to individual crops like sweet peas, tomatoes, and chrysanthemums. Leaf mould and peat can be used as a mulch and also to supply organic matter to the soil. Sawdust in a well-rotted condition is also useful for inclusion in compost and as a mulch. It is emphasised that it must be well-rotted, and it is advisable to apply a nitrogen fertiliser, such as sulphate of ammonia, at the same time.

Composting of organic refuse from house and garden is much practised by the amateur nowadays.

Compost-making.—The methods developed for making compost heaps are many and various; they depend on three basic principles, good aeration, plenty of moisture, and a nitrogen supply for the decomposition bacteria. A fairly simple method by which much garden and house refuse can be utilised is as follows. An area about 9 ft. by 4 ft. is marked out and all waste vegetable matter—weeds, lawn mowings, cabbage leaves, pea haulm, straw, dead leaves, and hedge clippings —are put in this area and trodden down. Care should be taken not to use diseased material but grass clippings and weeds which have been recently treated with hormone weed-killers may be applied. When the heap is about 9 in. thick it is sprinkled with sulphate of ammonia and superphosphate, at ½ oz. of each per square yard (2 oz. of each for a 9-ft. by 4-ft. plot) and any wood ash available, and then sprinkled with 4 gallons of water and covered with an inch of soil. This process is repeated with 9-in. layers of rubbish until the heap is about 4 ft. high, when it is better to begin a second heap. A sprinkling of ground lime may be given as each layer is added, but should not be applied until after watering to avoid reaction with the sulphate of ammonia.

The completed heap should be watered occasionally, and after about a month or six weeks, if time permits, it can be turned completely over, watered again, and re-covered with soil. The heap may then be left until rotted, and the compost can be dug in as required; any unrotted material can be used as a basis for a new heap. The time taken for rotting will vary with the time of year and material used, but generally a compost heap made during the summer should be available for autumn use, and one made during the autumn ready for spring use.

There are a number of compounds on the market, known as compost makers, which are said to accelerate the decomposition, but in general a heap made in the way described is eminently satisfactory, and although requiring a certain amount of labour, is the least expensive way of obtaining humus for the garden. This latter point is extremely important nowadays with the scarcity of animal manure and the high costs of both inorganic and organic fertilisers. Prices are, of course, not static, but comparatively the organic manures, such as dried blood, hoof and horn, and guano, are more expensive than the inorganic salts, but these lack humus, which is an essential of a well-cultivated soil.

General Fertiliser.—Many firms supply compound fertilisers containing given amounts of the main nutrients needed, in either liquid or powder form, and some are made up with quantities of nitrogen, potassium, and phosphorus suitable for specific crops like roses, tomatoes, and chrysanthemums. A general fertiliser which can be made up by the amateur is as follows:

7 parts by weight superphosphate.
5 parts by weight sulphate of ammonia.
2 parts by weight sulphate of potash.

All the ingredients are easily obtained fr local sundriesmen, and a mixture of this sort v supply a good general feed.

Green Manuring.—Another method of enrichi the soil with organic matter is green manuri which has been practised for some time by farm and can no doubt be adapted to the gardene purpose. Green manuring consists of plantin fast-growing catch-crop and ploughing the mat crop back into the soil. Legumes are especia good for this, as certain bacteria in their roots c "fix" the nitrogen in the air. Field peas, so at 4 oz. per sq. yd. and Italian rye grass at 2 per sq. yd. are commonly used, and clover a annual lupine are also suitable.

If sown after an early crop on land needi organic matter the green manure may be dug during late summer. Alternatively, if the land not being cropped at all during the year two gre manure crops may be grown; an early sowing field peas in April may be dug in during July, a a further sowing of field peas or Italian rye gr sown immediately after may be dug in follow the first few frosts.

New chemicals often appear on the market exorbitant prices and with fantastic claims as their value as "soil conditioners" and the li Contrary to this generalisation, in recent year chemical known as "Gibberellin" has been u to increase the growth of certain plants. It now available to the amateur, but should be us with care and mainly in a spirit of experimen tion, as no conclusive proof of its efficacy has been put forward.

GARDEN PESTS.

Every garden abounds in insects and other sm creatures, but comparatively few species are pe which feed on plants. The great majority quite harmless, while many are positively be ficial and help to keep the number of pests un control by catching and eating them. Ev good gardener should make it his business to able to differentiate between friend and f This is not always easy, but the speed of a cr ture's movements may often provide a cl Fast-running, active creatures, such as the bla ground-beetle or the centipede, are usually be ficial, while the slow-moving and sluggish on *e.g.*, wireworms, aphids and caterpillars, usually pests. This is by no means an infalli rule, but it is handy to remember when in dou

The good gardener should also get to know pests which are most prevalent in his district a which can be expected to crop up year after ye The first principle of good control measures is act while an infestation is still in its early sta and before a great deal of damage is done. Wh one knows what to expect, steps can be taken prevent an attack or to stop it developing serious proportions.

Also, from the experience of past years can often forecast whether a pest is likely to come numerous enough to make chemical tre ment worthwhile. Remember, insecticides become an expensive item, and there is lit point in using them if the damage is negligi In these circumstances insecticides may eventua increase the numbers of pests, since the treatme will also have killed off many of their natu enemies which had hitherto kept the pests un adequate control. In addition, good cultivati and general garden hygiene helps to reduce t numbers of pests.

The common pests of garden plants can roughly divided into four main groups.

I. Root Pests.—These destroy the feed mechanism of plants or tunnel into fleshy t roots, tubers, and bulbs. Attacked plants m poor growth, and may eventually wilt and die

Some insects are general root-feeders. These include (*a*) **Swift Moth Caterpillars**, soft, white caterpillars with reddish-brown heads; (*b*) **Chafer grubs**, large, C-shaped, whitish grubs with chestnut-brown heads; (*c*) **Wireworms**, long, cylindrical, yellowish-brown grubs with a hard shiny skin; and (*d*) **Leatherjackets**, greyish-black grubs with a wrinkled, leathery skin. These are particularly prevalent in recently cultivated grassland or in gardens surrounded by fields, and all attack the roots of a wide range of plants. Chafer grubs, however, are particularly fond of the roots of shrubs, and wireworms will often tunnel into potato tubers and other fleshy roots, whereas leatherjackets prefer the roots of grasses, and may cause browning on large patches of lawn.

Badly infested ground should be dressed with lindane dust when cultivating, working the dust into the top 4 in. of soil. Where this is not possible, *i.e.*, on lawns or around established shrubs, the liquid form of the insecticide should be watered into the soil.

Cutworms are stout, fleshy caterpillars, varying in colour from greyish-brown to dingy green. They feed on roots during the day, but at night come to the surface and feed at the base of the stems of plants, causing them suddenly to collapse and wither. Brassicas and lettuce are commonly damaged in this way. Infested ground should be dusted with D.D.T.

Millepedes are hard-skinned, cylindrical creatures, brown or black, with numerous short, hair-like legs. They are slow-moving and curl up when disturbed. They should not be confused with the active, long-legged centipedes, which are beneficial. Millepedes commonly extend the damage made by other pests, such as slugs and wireworms. They also bore into the sown seeds of peas and beans. During the day they hide in dark, damp places, such as long vegetation or under stones and pieces of wood. Such hiding-places should be removed or dusted with lindane. Drills for pea and bean seed should also be dusted before covering.

Weevil Grubs, small, curved, white grubs, may infest the roots of pot plants and plants in nurseries. Such plants should be removed, the pots cleaned, and replanted in soil which has been dressed or mixed with lindane dust. Where it is not practicable to remove the plants they should be watered copiously with a liquid form of these insecticides and soil dressed properly at the earliest opportunity.

Slugs need no description. They vary greatly in colour. The most destructive are the underground keeled slugs, small, grey-black in colour, which tunnel in roots, tubers, and bulbs. There are also several foliage-feeding species which rasp holes in the top parts of plants. Slugs like wet conditions, and much can be done to control them by ensuring that the soil is well-drained and that long, tangled vegetation is removed.

Poison baits can be bought or made by mixing 1 oz. metaldehyde with 3 lb. bran (or bonemeal for peeled slugs). The bait is sprinkled over the infested ground or distributed in small heaps and protected from the rain. There is also available in the market a metaldehyde spray for dealing with the foliage-feeding types.

Cabbage Root Fly attacks brassicas and wallflowers. The small white maggot eats away the side roots and tunnels in the main root, causing the plant to wilt and collapse. The roots of young seedlings should be dipped in lindane before planting out. Alternatively, the plants can be given a drench of lindane within four days of planting out.

The maggots also tunnel in radishes and turnips, and this can be avoided by dusting the seed drills with lindane.

Carrot Fly.—The maggot of this fly tunnels in carrots and parsnips. Where the pest is serious it is best to delay sowing until the end of May, if possible, seeds should be sown in exposed, windy places, which are avoided by the egg-laying flies. Seedlings should be dusted or sprayed with lindane when 2–4 in. high, particularly in late May or early August, the peak periods for egg-laying.

Onion Fly maggots tunnel into the bulbs of onions, leeks, and shallots, causing the foliage to collapse. Dig out attacked plants carefully, ensuring that parts of them are not left in the soil, and burn them. To prevent attacks dust around the seedlings with lindane when they are at the "loop" stage, *i.e.*, about 1 in. high, and again ten days later.

Narcissus Bulb Flies are serious pests of narcissi and also snowdrops and other bulbous plants. The maggots burrow in the centre of the bulbs, causing them to rot. All soft bulbs should be burned and the remainder immersed for three hours in a solution of lindane containing a wetter. To prevent future attacks and a reinfestation, dust around the necks of growing bulbs with lindane at fortnightly intervals from the end of April until the end of June.

Insects which feed above ground include:

II. Sucking Pests pierce the tissues of plants with needle-like mouth parts and suck the sap. This devitalises the plant, checks growth, and causes wilting. Some species cause distortion of leaves and young shoots, and aphids, suckers, scale insects, and mealy bugs excrete a sugary fluid which disfigures the foliage, attracts ants, and allows the growth of sooty moulds.

Aphids, *i.e.*, blackfly, greenfly, etc., are serious pests which attack almost all plants and multiply rapidly in warm weather. They feed on the shoots and undersides of the leaves, and many species are responsible for the transmission of virus diseases. Infestations should be treated as early as possible. Malathion, lindane, D.D.T emulsion, and nicotine are all good sprays to use, and should be applied to the undersides of the leaves. With the advent of these sprays the control of aphids on roses and broad beans, for example, is no longer a serious problem.

Tree fruits should be sprayed when the buds are bursting and again when the flower buds are still green. Currants should be treated at the "grape" stage, but lindane should not be used on this fruit. Tar oil, applied to deciduous woody plants while they are completely dormant, will kill the overwintering stages of these and many other pests. It does not, however, give a good winter control for Woolly Aphid on apples. This pest is best controlled by spraying at the pink-bud stage with B.H.C. with a succinate spreader added. Small colonies on the bark can be eradicated by painting with 10% tar oil.

Some aphids feed underground on roots, particularly of lettuces, currants, and cacti. Where practicable, infested plants should be lifted and the roots cleaned and sprayed before replanting in clean soil. Otherwise water them copiously with malathion or lindane.

Scale Insects are often found in greenhouses, but also occur out-of-doors on trees and shrubs. Flat or dome-shaped, these creatures spend most of their lives immobile, and they do not at all resemble insects, or even appear to be alive. Again tar oil is useful for killing the overwintering stages on deciduous woody shrubs which are dormant. Plants which are in leaf should be sprayed with malathion or nicotine/white oil emulsion two or three times at fortnightly intervals. These substances are more effective if as much as possible of the scale is first removed by means of a sponge, brush, or scraper with water in which soft soap has been dissolved. **Mealy Bugs** are common pests of greenhouse plants, and should be given the same treatment as scale insects.

Capsid Bugs are very active insects which cause considerable damage to fruit trees and bushes and also to various ornamental plants, principally

chrysanthemums and dahlias. They feed on the young leaves, causing distortion and raggedness, and on the buds, which later produce misshapen blooms. These insects, green or reddish in colour, can be controlled by spraying with lindane or D.D.T. when the flower buds are still green (tree fruit) or with D.D.T. at the " grape " stage (currants). Herbaceous plants should be sprayed two or three times at three-weekly intervals, starting when the plants are young and before the damage is seen. The ground under the plants should also be sprayed to kill those insects which fall off during treatment.

Leafhoppers are small, yellowish-green insects like aphids but much more active. They feed on the undersides of the leaves of a variety of plants, causing them to become speckled with yellow. Roses are commonly attacked. The treatment given to capsids on herbaceous plants will control these also, the sprays being directed to the undersides of the leaves.

Whiteflies are serious pests in greenhouses, and also occur out-of-doors on rhododendrons and other evergreen shrubs. The adults are like miniature moths with white wings, and the young are small, scale-like creatures, generally greenish in colour, which feed without movement on the undersides of the leaves. To control this pest D.D.T., lindane, or malathion should be used as a spray or smoke, two to three applications being given at fortnightly intervals.

Red Spider Mites are extremely small creatures, red or greenish in colour and just visible with the naked eye. They feed on the undersides of the leaves of many greenhouse and outdoor plants, including fruit, causing the leavcs to turn sickly yellow. Control is difficult, the most effective materials being malathion, derris, summer oyl-cides, or azobenzene smoke. The directions on the labels of these products should be followed carefully.

III. Biting Insects have chewing and biting mouth parts which are used to cut away pieces of plants.

Caterpillars (the young stages of moths and butterflies) are the best-known pests in this group. They vary in size and colour according to the species, and most plants are liable to be attacked. These should be sprayed or dusted with D.D.T. or derris as soon as damage is seen. On fruit trees D.D.T. should be used when the fruit buds are still green, and again at the pink-bud stage if the infestation is serious.

The Codling Caterpillar, which tunnels in apples, is controlled by spraying with D.D.T. at the end of June and again three weeks later. Since this latter treatment tends to encourage red spider mites, it is advisable to add to the D.D.T. one of the materials recommended for these pests.

Sawfly Caterpillars are very similar to those above, and commonly attack gooseberry and rose foliage. They can be controlled by spraying with D.D.T., derris, or lindane. Attacks by the **Apple Sawfly**, which burrows in young apples and forms ribbon-like scars on the skin, can be prevented by spraying with lindane seven days after 80% of the blossom has fallen.

Beetles and **Weevils** which feed on foliage are usually best controlled by spraying or dusting with D.D.T. To kill the tiny **Flea-beetles** which eat small holes in the seedlings of brassicas and turnips, treat the plants at fourteen-day intervals until they reach the " rough-leaf " stage.

The golden-brown **Raspberry Beetle**, which feeds on the flowers and whose grub tunnels in the fruit, is eradicated by D.D.T. or derris applied ten days after full bloom and again ten days later. For other common pests in this group, *e.g.*, **Vine Weevil**, **Clay-coloured Weevil**, **Pea and Bean Weevil**, etc., apply the D.D.T. as soon as the damage is first seen.

Earwigs feed at night on the foliage and flo petals of many plants. They hide by day ins flowers, in the folds of leaves, and in nooks crannies on the ground, under flat stones, These pests are killed by D.D.T., applied to plants (but not to open flowers) and to t hiding-places.

Leaf Miners are very small grubs which tu between the upper and lower surfaces of lea forming pale blisters, as on lilac, holly, cel etc., or long, twisting galleries, as on chry themum, pea, and tomato. In small infestati the affected leaves should be picked off burned. Otherwise spray with lindane as s as the damage starts, giving three application fourteen-day intervals.

IV. Eelworms are microscopic pests which invisible to the naked eye. They are able to for very long periods without food and are tremely difficult to eradicate. The most comm species are:

Stem and Bulb Eelworm, which infests narcis phlox, strawberry, hyacinth, onion, and o plants. Infested plants show distorted fol and dwarfing and gradually deteriorate. T can only be sterilised by immersion in hot w kept at well-defined temperatures for one to t hours, but expert diagnosis and advice should obtained before this or any other contro attempted. Infested ground must be kept c of any host plants for at least three years to sta out the eelworms.

Chrysanthemum Eelworm causes the forma of yellowish blotches between the veins of chry themum leaves, which later turn black and d off. In severe infestations the blooms are un sized and malformed. Expert advice should obtained before control measures are attemp

Potato Root Eelworm is a serious and widesp pest of potatoes, causing the plants to bec stunted and sickly, giving very poor yields. pest can only be kept in check by crop rotat potatoes being grown on the same ground once in four years. This is difficult in s gardens, and where land becomes heavily infe the only remedy is to rest it from potatoes fo least five years.

The Purchase and Use of Insecticides.— ensure that an insecticide will do what the ma claims, it is advisable only to buy brands wi have been tested and approved by the Minis of Agriculture. This can be ascertained by presence of an Approval Mark (T30) on the la Read the directions and follow them carefu Over-strength insecticides can cause damag plants, and certain plants (usually listed) ca injured by some insecticides at any concentrat *e.g.*, cucumbers, marrows, etc., by D.D.T. lindane. Never apply insecticides to flower full bloom, otherwise many valuable pollina insects will be killed.

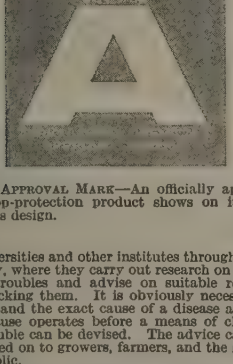
DISEASES OF PLANTS.

Plant diseases are important because they cause great loss not only in growing crops but in the produce after it has been harvested stored. The skill in growing crops is waste they are destroyed by disease, and many pe know the wastage of potatoes through blight dis in winter stores and rotting of onions when decay through neck rot disease. For t reasons the keen gardener must take notic

diseases and use the knowledge available to him in checking them wherever possible.

The most important point to remember about plant diseases is to recognise the first signs so that the remedy can be applied at once. In greenhouses this is of great importance because the atmosphere is warm and moist, and in such conditions diseases flourish. It must also be remembered that the same crop is often grown in the same soil in a greenhouse so that we get a build-up of disease, and this causes the well-known "soil sickness." This means that new soil must be brought in or the old soil enriched and also sterilised by steam or by chemicals. Even frames and propagating pits require periodic cleaning up by a disinfection treatment.

Unlike insect pests, the actual cause of a plant disease cannot be seen with the naked eye, and microscopic examination is required for its detection. The scientists who study diseases are called plant pathologists, and these are stationed



THE APPROVAL MARK—An officially approved crop-protection product shows on its label this design.

at universities and other institutes throughout the country, where they carry out research on various plant troubles and advise on suitable remedies for checking them. It is obviously necessary to understand the exact cause of a disease and how that cause operates before a means of checking the trouble can be devised. The advice can then be passed on to growers, farmers, and the gardening public.

The presence of disease in most cases can only be detected by the symptoms shown by the affected plant, which is called the "host" plant. The actual cause must then be determined by careful examination in the laboratory, which is done by the pathologist.

Plant diseases in general are divided into three classes as follows: 1. Fungus and Bacterial. 2. Virus. 3. Functional Disorders.

1. Fungus and Bacterial Diseases.—The first kind called fungus diseases are caused by the attack of fungus parasites; examples being the well-known club root of cabbages, potato scab, apple scab, and plum brown rot. These parasitic fungi are microscopic and composed of fine threads, but they attack plants and penetrate them either through wounds (insect bites, hail damage, pruning cuts) or directly through the surface cells (epidermis). The threads grow into the plant, killing the cells and absorbing their contents. There is usually some discoloration or even decay of the tissues around the point of infection, but it is possible for the plant to show distress in one part although the parasite is at work some distance away. Examples are silver leaf in plums and the honey fungus, which kills trees by attacking the roots.

The fungus spreads by means of spores which are equivalent to seeds in flowering plants but which are microscopic in size. These spores are produced on the surface of the plant in enormous numbers and are blown (wind), splashed (rain), or carried (insects, etc.) in all directions to attack on other healthy plants, where they germinate and spread the disease. This occurs in the growing season, but when winter approaches, the parasite forms tough, resting bodies of one kind or another, and these are resistant to extreme cold.

They overwinter in the soil or in the surface of tree bark, etc., so that in the following spring they can germinate and cause disease again. So we get the reappearance of such troubles as damping off in seedlings, scab in apples, brown rot in apples and plums, foot rot in peas, wart disease in potatoes, mildews on all kinds of plants, and so on. This question of soil contamination by overwintering spores is one of the most serious in the fight against plant disease.

The signs of fungus and bacterial diseases are varied, and may show as yellowing, silvering, brown spotting, or blackening of leaves (potato blight, rose black spot, celery leaf spot, antirrhinum rust), as stunting (cabbage wire stem), as pustules and cankers in stems (coral spot, apple canker), as gumming or dieback in branches (rose canker, plum dieback), as galls, warts, witches brooms, or other malformation (club root in cabbages, crown gall, leafy gall, peach leaf curl), as dry or soft rots of fruits, tubers, vegetable bulbs, and corms (gladiolus dry rot, potato dry rot, iris rhizome rot, celery heart rot), and many other abnormal conditions. Sometimes only a part of the plant is affected and can be removed, *e.g.*, branches showing attack by coral spot or one of the large bracket fungi seen on trees, these having gained entrance through a wound.

2. Virus Diseases.—This class of disease is becoming increasingly important as more is discovered about them, although research on them is a comparatively recent development. A virus disease is caused by infection with a virus, and the exact nature of this is not yet clearly understood, but it is so small that it cannot be seen with ordinary microscopes. Its detection is therefore not easy, but when the sap of a virus-diseased plant is injected into a healthy one it causes the disease.

In nature this spread is brought about by biting and sucking insects, which are referred to as **Vectors.** They transmit the virus by feeding on infected plants and then travelling to healthy ones, on which they feed and so spread the disease. Most viruses are transmitted by aphids (greenflies).

In the garden and nursery they can be carried from plant to plant by pruning knives or by the fingers in the process of trimming plants such as tomatoes, melons, or cucumbers or by the use of the knife in taking cuttings. In general, the virus does not kill a plant quickly but tends to cripple it and cause a slow deterioration. Infected plants cannot recover but remain, sometimes for years, as sources of infection on which insects feed and carry on the disease. So viruses may increase in lily stocks, strawberry beds, and raspberry plantations unless virus-infected plants are removed and aphids strictly suppressed.

The signs of virus disease are of different kinds, but the commonest are those of the type called mosaic, in which the leaves show a mottling with light-green or yellow patches scattered in irregular fashion on the darker green of the leaf. There may be also some reduction in the leaf blades. These symptoms can be seen in the mosaic of cucumber, vegetable marrow, lettuce, cabbage, turnip, tomato, delphinium, primula, dahlia, apple, raspberry, and many other common plants. In some, such as lilies, daffodils, and onions, the mosaic is more in the form of stripes down the leaf blades.

Another virus symptom is flower "breaking," where the normal colour of the petals is broken by streaks and spots of white, and this can be seen in tulip, wallflower, pansy, stocks, or carnations affected by the mosaic virus. Other viruses cause bronzing of the top leaves (as in tomato spotted wilt) or small light-coloured rings arranged in concentric circles (as in dahlia ring spot) or even reduction of leaves until they are tendril like (as in tomato fern leaf). Sometimes there is malformation or even proliferation, producing innumerable stunted shoots, as in blackberry dwarf disease.

The important point to note about these virus diseases is that every part of the plant is quickly

infected, so that the sap is infectious to other plants of the same kind. The virus is present in all parts, and for this reason it is useless to propagate from a virus-infected plant. This means that all the scales and offsets from bulbs such as lilies and tulips, all the tubers from potatoes, and all cuttings from herbaceous plants which are taken from a virus-infected plant are useless, because they will carry the virus. They should be destroyed, and the only exception is where the plant is greatly valued, in which case seed can be taken from it before it is destroyed. In general, viruses do not travel in the seed, and only in one or two cases is seed infected, and this only in negligible quantity.

3. Functional Disorders.—This third class of disease is often called non-parasitic, because unlike the previous two kinds there is no parasite involved, and these troubles are therefore not infectious. They are due to faulty cultivation or unsuitable environment, in which soil conditions or climate affect the plants adversely. In this group we include cases of unsatisfactory growth due to waterlogging, drought, frost, high temperature, damage by fumes or atmospheric pollution, or even excess lime.

Perhaps the most important kinds of trouble in this class are the so called **Deficiency Diseases**, where the plants suffer from shortage of some important food. This may be one of the common food substances, such as nitrogen, potash, or phosphate, and details will be found under the section on manures and fertilisers (T26).

CONTROL OF DISEASES.

1. Garden Hygiene.—The control of plant diseases can be dealt with only briefly, but to begin with we must emphasise the value of good cultivation as an insurance against losses from disease. Robust plants are better able to stand up to disease than sickly ones, and everything in the way of proper drainage, soil aeration, proper spacing, sensible feeding, and so on, will help to keep the plants vigorous, and this is the first line of defence against diseases. Garden hygiene is important, weeds need to be kept down, wounds in trees and shrubs covered with a good paint against infection, new stocks examined carefully, seed bought only from reliable sources, diseased plants burnt, and dead material regularly removed from plants, especially in greenhouses.

2. Soil Sterilisation.—There are other precautions, among which the sterilisation of the soil in greenhouses by means of steam or chemicals is of some importance. Outdoors this is not possible, but rotation of crops is a most useful system in helping to avoid disease. Disinfection of frames, propagating pits, and seed boxes by formalin or cresylic acid are other useful measures.

All these operations aim at destroying the resting spores of fungus parasites responsible for such diseases as tomato leaf mould, gladiolus dry rot, damping off in seedlings, root rots, and downy mildews of many kinds in young plants such as stocks, cheiranthus, cineraria, tomato, aster, and calceolaria when grown in boxes or pots.

3. Disease Resistant Plants.—The use of disease-resistant varieties of plants is very desirable, but there are not many kinds available, and often the resistant kind does not possess flowers or fruit of such fine quality or flavour as the more susceptible kind. The outstanding success of this kind is that of potatoes immune to the dreaded wart disease, and these can be grown safely in the most heavily infected land. There are antirrhinums resistant to rust disease, and there is resistance in some degrees in the case of delphinium mildew, potato blight, tomato leaf mould, and some others. Research goes on to discover still more, because any such plants are always worth a trial.

4. Treatment of Seeds and Bulbs.—For seed-borne diseases seed treatments may be done with an organo-mercurial seed dressing, or even b immersion of the infected seed in warm water.

In some diseases, for example, tulip fire, v can protect the bulbs from the danger of infecte soil by raking in a powder such as "Botrolex" whe planting the bulbs, and a similar treatment done with calomel dust against club root in bed intended for sowing brassica seeds.

5. Fungicides.—Even after all this, a disea may still appear in the crop, and more dire action must be taken. It is then necessary protect the plants by means of a Fungicide. Th is a chemical which is poisonous to fungus parasit but which will not harm the crop plant (host Fungicides are used as wet sprays or in powd form as dusts, and they are sprayed or dusted over the plants to protect them from infection b diseases.

The object of the treatment is to cover the plan with a film of the fungicide so as to protect the st healthy ones. To help the spray fluid to spre over and adhere to the foliage another substanc called a wetter, spreader, or sticker, is added the spray, but sometimes this is already includ by the manufacturer.

5. (*a*) **Sprays.**—Sprays are applied by means machines called sprayers which vary from sma hand-syringe types giving a continuous jet of spra to those pumped up to a pressure and carried the back (knapsack machines), and so on to t large machines driven by a petrol engine, whi deliver the spray at a high pressure. It is nece sary to have a suitable nozzle giving a fine mis like cone of spray which settles on the foliage a is not wasted.

5. (*b*) **Dusts.**—Dusts are similar chemicals pr duced in such finely divided form that the powd can be blown over and on the foliage almost like fog. This is best done after a shower of rain after a heavy dew. The machines used are f more varied in design than spraying machine There are small hand dusters worked either like small pump or like a bellows, of which the "Acme is a good example, and there are those which a carried on the back and worked as a doub bellows action or on the front of the body with rotary-fan action. It is important in gardens clean and dry the machines after use, and sm sprayers may be best put upside down to dra for a time after use.

The substances used as sprays and dusts again plant diseases for many years have been copp and sulphur and their compounds. Perhaps t best known copper-containing spray is "Bordeau Mixture," which is still a good spray, but whi has been largely replaced by colloidal copp available under trade names like "Coppicide for such diseases as tomato blight, etc. Sulphur used extensively as lime-sulphur against app scab and as colloidal sulphur against the powde mildew diseases. As dusts, copper is mixed wi lime to give copper–lime dust and sulphur is us alone either as flowers of sulphur or green sulphu

5. (*c*) **The Newer Fungicides.**—In recent yea much research has been carried out in tests to s whether other chemicals have value as fungicide and the search has been in the field of organ chemistry and among all kinds of these chemica Tests of this kind take a long time, but a few su stances have already been picked out as showi great promise, and we can mention "Captan which is so good against apple and pear sca "Zineb" against tomato leaf mould, onion milde and tulip fire, "Karathane" against any of t powdery mildews, such as american gooseber mildew, strawberry mildew, vine and peach m dews, as well as the same diseases on ornament roses, delphiniums, michaelmas daisies, and t like.

6. Control of Viruses.—The control of vir diseases is very different, because in this case t only spray treatments likely to be of use are tho designed to keep down insects. The other nece sary control measure is to remove and destroy t virus-infected plants, which are a danger as sourc of infection.

This is best done when the plants are young, so that any young marrows, cucumbers, dahlias, delphiniums, sweet peas, lupins, lilies, etc., which show virus symptoms as commonly revealed in leaf mottling and poor growth should be removed as soon as detected. Propagation should be done carefully, so that young stock is not propagated from stocks of strawberries, raspberries, and all kinds of herbaceous perennials which show signs of virus infection. Even the knife used for taking cuttings should be wiped occasionally on a rag dipped in a good disinfectant.

7. Prevention of Functional Disorders.—In the case of Functional Disorders (non-parasitic diseases) it is not always easy to advise remedies. Where the soil conditions are faulty attention can be directed to improving drainage if necessary or counteracting dryness by digging in humus, irrigating, and general mulching. Dryness at the roots of tomatoes causes loss of fruit, and so does extreme dryness in the air of the greenhouse, but these should be adjusted fairly easily.

Hail damage can spoil many crops, but robust foliage may help a little to lessen the damage. Late frost damage to fruit in some areas can be lessened by various methods of cultivation and planting. The effects of drought can be aggravated by shortage of certain foods, especially potash, so that even here some attempt can be made to avoid loss. Excess liming may cause food shortages by causing the appearance, in the leaves, of a yellowish or even whitish colour, which is known as lime-induced chlorosis. The real reason may be lack of iron or manganese due to the excess lime in the soil, but recently very good results at counteracting this condition have been obtained by using the substance known as "Sequestrene Plus."

Another method of treating these food shortages is to spray the young foliage in early summer with the required element in a very weak solution. They can even be included in sprays used for keeping down diseases or pests. It must not be forgotten that even the ordinary foods, such as nitrogen, potash, and phosphate, may sometimes be in short supply, and the effect can be seen by the trained plant pathologist. In these cases the effect may not always show clearly in the growing crop, but may appear long afterwards in the stored fruits and vegetables, which as a result deteriorate and break down long before they are required for use.

The present-day methods of cultivating large numbers of the same plant in one spot tend to increase the risk of large-scale disease attacks. Modern plants may be highly bred and selected for great purity of strain. Indeed, they have often been chosen for fine quality and flavour, with little regard to their ability to resist disease, so that the gardener must always be ready to give them the protection they may need.

USES OF MODERN WEEDKILLERS

The eradication of weeds by chemical means is one of the greatest advances of recent years albeit the value of herbicides is still unappreciated by most gardeners. With a planned programme, all cultivated ground and lawns can be kept free of weeds without hoeing or any other sort of manual cultivation.

Occasionally troubles have arisen in not following makers' instructions. Sometimes the damage has been most unfortunate, as the majority of herbicides are toxic, in varying degrees, to a wide range of plant life. In the main, controls are determined by circumstance, as typified in the following cases:

Asparagus Beds.—Annuals and top growth of perennial weeds can be controlled with dreaylic acid in the autumn and before the asparagus appears in the spring. In beds free of perennials a first-class control of weeds can be maintained with Simazine applied in the early spring.

Where annual and perennial grasses predominate, Dalapon or Diquat will give good control. As for bindweed, this may be eradicated by watering the foliage with 2,4-D in late July or August taking care to avoid contact with the asparagus stems and particularly the fern.

Fruit Garden.—Around blackcurrants, gooseberries, raspberries, apples, and pears, grasses can be killed with Dalapon. Once clear of perennial weeds, annuals may be controlled effectively with Simazine. Alternatively, weeds may be killed with Diquat, making applications as necessary throughout the season.

Garden Paths.—On any surfaced path or drive a first-rate control of weeds can be maintained by watering with a residual herbicide such as Simazine. As this preparation is virtually insoluble in water, it does not seep through the soil as sodium chlorate would, and therefore it can be used near garden crops and grass edgings. Further to this, it is not easily washed from the soil and remains active near the surface for up to twelve months. Notwithstanding, the herbicide must be used with proper care.

A dilute solution of sodium chlorate with 4–6 ozs. to a gallon of water may be applied, but it is liable to affect plants near by and, for this reason, application should be confined to the centre of the path, thereby leaving room for the chlorate to seep through the soil.

Lawns.—The majority of weeds in turf can be eradicated easily with formulations of 2,4-D or M.C.P.A. (*see* **Finding List**). In particular, daisies, dandelions, plantains, and most broad-leaved weeds are susceptible although it may be necessary to repeat the dose after 10 days. The best time to do the work is on a warm, fine day in the spring when the plants are growing actively and there is the prospect of fine weather to follow for twenty-four hours. The action of the herbicides is rapid, and grass may be cut after a couple of days, composting with mowings in the normal way. It appears that the hormones are not injurious to bacterial life in the soil and in a few weeks break down into harmless substances.

Where bulbs are naturalised in grass, steps to control weeds should not be taken until the foliage of the bulbs has died down and the bulbs are dormant. Thus, as a general rule, control measures are best applied throughout July.

To deal with weeds in turf where there arises the danger of the spray—or even a drift from it—touching cultivated plants near by, as, for instance, on grass paths in a rose garden, then a wax bar impregnated with a hormone can be lightly drawn over the turf. Such bars are available at a reasonable price under trade names like "Supplex Touchweeder."

Some weeds are resistant to normal doses of hormones and need special treatment. These are mostly mat-forming plants of low-growing habit which are not cut off by mowing. Typical examples include mosses of all sorts, pearlwort, speedwell or veronica, yarrow, and yellow-flowered clover. Here, the main control must be in the use of lawn sand, a good mixture of which can be made up with:

2 parts by weight sulphate of ammonia.
1 part by weight sulphate of iron.
13 parts by weight LIME-FREE sand.

Where moss is the most prevalent weed, to the mixture should be added sufficient superphosphate to give 1 oz. of it per sq. yd. for the area to be treated. A hundredweight of the lawn sand plus superphosphate can be made up for about 17*s*. and is sufficient to treat about 450 sq. yds. at 4 oz. per sq. yd.

Applications to patches of the weeds should be made when the turf is damp and there is the prospect of fine weather; if a period of drought follows an application, then water should be applied to avoid serious scorching. Repeat the treatment as necessary throughout the growing season. Linked with this "spot" treatment, the growth of grass must be encouraged, as this will tend to smother low-growing weeds. Thus, in the early spring when the turf is wet, feed with a

mixture of equal parts of superphosphate, sulphate of ammonia and dry soil at 2 oz. per sq. yd. over the whole area and repeat after a month, if desirable. In addition, do *not* shave off the grass by close cutting; instead, the blades of the mower should be set reasonably high for a whole season.

Where fertility is low, clovers often predominate in turf. The Dutch clovers with white—or pink—flowers and a white-angled band towards the base of each leaflet, can be eradicated with Mecoprop. Afterwards the turf should be fed with nitrogenous fertilisers like soot and sulphate of ammonia, to discourage reinfestation. Other types of clover found in turf are species of *Trifolium*. Compared to the Dutch clover, these have a tight, bunched habit of growth and yellow flowers. All of them are resistant to hormones and, in addition to manurial treatment, should be treated with lawn sand.

Lakes.—It sometimes happens that aquatic plants with large floating leaves, such as water lilies, get out of hand. Here, control can be established by cutting off the foliage with a long-handled appliance like the "Corypu Water Scythe." The work should be done early in June and repeated as often as any fresh growth is seen.

Bulrushes are difficult to eliminate, but can be destroyed by digging out the roots when the level of the water permits. Dalapon has been found to give a control; applications should be made, with a wetting agent added, when the rushes reach maturity.

Ponds.—Problems of weed control in ornamental ponds are often not easy to solve. Where duckweed is prevalent this small floating plant can be eliminated by sweeping the surface of the water at regular intervals. If this practice is carried out thoroughly much of the vegetative growth will be eliminated, and the plant will not be able to form resting bodies whereby it overwinters. Once a control has been established, further spread of the plant can be prevented by introducing a few moorhens or ornamental ducks.

The most common of unwanted plants in pools is blanket weed. There is no single means of dealing with this plant, for its spread is governed, to a certain extent, by unbalanced plant and anima life in the water. With this fact in mind, water lilies should be established so that their foliage shades about 25 per cent of the water. In addition, a few oxygenating plants should be introduced from local ponds or streams and a supply of goldfish added. Blanket weed is usually found in pools where the water gets overheated in summer; for this reason, the average depth of garden ponds should be a minimum of 2 ft. and preferably a minimum of 3 ft.

Rose Beds.—A complete control of annual weeds among roses can be obtained with Simazine. Here, the salient point is to apply the herbicide immediately after pruning in March *before* any weed growth starts. Alternatively, Diquat can be used in April or early May and the application repeated as necessary.

Shrubberies.—With a shortage of labour, beds of shrubs are often weed infested. Perennials can be eradicated with Diquat and annuals controlled by this treatment as they appear. Alternatively, once the perennials are removed, the ground can be kept clear with Simazine used in the early spring.

Much to check weeds in shrubberies can be done by mulching the surface of the soil with heavy dressings of peat, fallen leaves, or sawdust; if the weeds push through the mulch, a second application should be made at once.

Vacant Ground.—On land free of crops all plants can be killed by watering the herbage with sodium chlorate at 1 lb. to a gallon of water. In some cases repetition may be necessary. When using this method it should be remembered that treated ground will remain toxic to plant life for a period of up to six months; if doubt exists about the persistence of the chlorate in the soil, then it is advisable to wait for the appearance of annual weeds before planting.

Apart from its persistence, sodium chlorate is prone to seep through soil and affect plants for some distance away. To avoid danger of fire from clothes being soaked in a solution of t chlorate and then dried, it is prudent to use formulation with an additive to reduce the ri of fire. (*See* **Finding List.**) Where couch grass predominant then the best control is to be o tained with Dalapon.

SPECIAL PROBLEMS OF WEED CONTRO

Bindweed.—Probably the most ubiquitous of garden weeds. Up to the present time the ma control has been to carefully fork out the roo as new growth is seen; if this is done methodical the plant can be eliminated within a reasonab time.

Lately, chemicals have come to the fore, a bindweed may now be eliminated by watering painting the foliage with a formulation of 2,4- when the annual growth has nearly reache maturity. Thus, first applications can be appli in July and the treatment repeated, if necessar to good effect. Where the weed is among cul vated plants, the herbicides must be applied wi a paint brush or the foliage rubbed with a clo damped in a solution. When doing this rubb gloves should be worn.

Blanket Weed.—*See* **Ponds.**

Bracken.—Horticulturally, control is not a b problem, and in limited areas it is easily de with by repeatedly cutting the aerial stems with grass hook as the first fronds open. This practi will exhaust the underground food supply of t plant, and gradually it will die out. The you fronds are rich in plant food and, while still gre and fresh, they should be composted. N chemicals will offer a reasonable control of th plant and, indeed, it is best dealt with by cutti and final digging out of the roots.

Couch Grass.—Where the soil is light and ten to be low in fertility, it is often found that th is a difficult plant to eradicate by cultural mean If the long, underground stems are forked out the conventional manner and left on the surfa to dry, the roots may be composted to advanta and a good control established. To prevent rei festation, manures and fertilisers should be appli generously and the ground kept hoed regularly.

Chemically, couch grass can be killed easily b watering the foliage with Dalapon.

Ground Elder.—Without question this is one the worst garden weeds and, whether or not t fact is pleasant or acceptable, it is indubitably weed of neglected ground. In varying degrees it resistant to hormone weed-killers of all sor On ground free of crops it may be reduced by application of sodium chlorate, as explained in t paragraph **Vacant Ground.** The first treatme should be made as soon as growth starts in t spring and repeated if the desired effect is n abundantly clear. When ground elder is to found among herbaceous plants the cultivat plants must be lifted out and the weed remov by repeated hand-forking.

In shrubberies reasonable control can be had b smothering the young growth in the spring with thick dressing of peat, leaf mould, baled straw, sawdust. If growth penetrates the surface dres ing it will be found that the etiolated shoots a not difficult to remove by hand, or a second lay can be applied to complete the treatment.

Alternatively, the foliage of ground elder can watered with Diquat and the treatment repeat once or twice during the growing season.

Horsetail.—This is sometimes erroneously call marestail and on poor, sandy soils it is often common weed. Fortunately, recent experimen have proved that it can be easily controlled b spraying or painting the *mature* growths with formulation of 2,4-D, taking care, of course, keep the spray off cultivated plants near by. the appearance of horsetail is symptomatic of lo fertility, manurial treatment should be carri out on a generous scale. Where the weed growing among cultivated crops, individual ste must be treated separately as recommended f bindweed.

Marestail.—*See* **Horsetail.**

Moss.—*See* **Lawns (T33).**

Nettles.—It is difficult to understand why the perennial nettle is so abundant as it is immediately responsive to applications of 2,4-D and 2,4,5-T made any time during the growing season. The annual nettle is usually proved a denizen of rich, light soils and may be eradicated with mesylic acid, Diquat or 2,4-D.

Oxalis.—Of all weeds this is probably the most difficult to destroy. It is easily identified by its large, trifoliolate leaves like that of clover. Unlike other weeds, oxalis cannot be efficiently removed by hand, as this disturbs the bulbils clustered around the base of the stem of mature plants. On ground free of crops, sodium chlorate can be applied in March (*see* **Vacant Ground**). Perhaps a second application may be necessary, but, even so, control may not be complete. Among shrubby plants, it may be possible to eradicate the weed by smothering, as suggested in the paragraph on ground elder.

The foliage can be killed with Diquat and, by repeated applications, this may constitute the best means of control.

Speedwell.—*See* **Veronica.**

Veronica.—This procumbent, blue-flowered weed of turf is sometimes know as speedwell. Being resistant to hormones, its control may only be established with lawn sand. *See also* **Lawns.**

Woody Plants.—With or without the addition of 2,4-D, these may be killed with 2,4,5-T. This hormone is particularly useful on bramble, gorse, ivy, and other unwanted shrubby plants. It is necessary to thoroughly saturate the foliage of deciduous trees, and the best results are obtainable when the leaves are fully mature but not starting to die off. In the case of ivy, the dormant shoots should be generously sprayed for the best results.

Yarrow.—A weed found in many lawns where its presence often signifies low fertility. Control with lawn sand. *See* **Lawns (T33).**

Summary.—From these notes it will be seen that there are many aids for dealing with weeds. The salient point is to get the *right* method for each plant. Equally important is to check the season why certain weeds grow profusely under some conditions. Very often this natural tendency can be counteracted as in the case of phosphatic fertilisers against moss and in the application of organic manures and chemical fertilizers where horsetail and yarrow are concerned. *See* **T35.**

HORTICULTURAL SOCIETIES.

There are many specialist societies in Britain. Detailed information on particular plants is normally available from them, and membership is open to all wishing to join. The most prominent societies are:

Alpine Garden Society
Sec. Michael Upward, 58 Denison House, 296 Vauxhall Bridge Road, S.W.1.

Auricula and Primula Society, The National
Sec. A. Marlow, 52 Epsom Lane North, Epsom, Surrey.

Begonia Society, The National Society of England and Wales
Sec. F. J. Martin, 50 Woodlands Farm Road, Erdington, Birmingham 24.

Cactus and Succulent Society of Great Britain
Sec. D. V. Brewerton, 26 Chester Road, Ilford, Essex.

Camellia Society, The International
Sec. Charles E. Puddle, V.M.H., Bodnant, Tal-y-Cafn, Denbighshire.

Carnation Society, The British National
Sec. E. G. Cook, 1 Evelyn Rd., Worthing, Sussex.

Chrysanthemum Society, The National
Sec. S. G. Gosling, 65 St. Margaret's Avenue, Whetstone, N.20.

Daffodil Society
Sec. D. J. Pearce, College of Ascension, Selly Oak, Birmingham, 29.

Dahlia Society, The National
Sec. P. Damp, 26 Burns Road, Lillington, Leamington Spa, Warwickshire.

Delphinium Society, The
Sec. C. J. H. Topping, B.A., Ph.D., 5 Park Lane, Sevenoaks, Kent.

Floral Arrangement Societies of Great Britain National Association of
Sec. Mrs. F. C. Dobson, 21A Denbigh Street, London, S.W.1.

Fuchsia Society, The British
Sec. W. G. Sharp, Rydal, The Green, Gt. Bentley, Colchester, Essex.

Gladiolus Society, The British
Sec. J. G. Lord, 25 Kimpton Avenue, Brentwood, Essex.

Hardy Plant Society
Sec. Miss B. White, 10 St. Barnabas Rd., Emmer Green, Reading, Berks.

Heather Society, The
Sec. Mrs. C. I. MacLeod, Yew Trees, Horley Row, Horley, Surrey.

Iris Society, The British
Sec. Mrs. D. J. Waters, 87, Roglan Gardens, Oxley, Watford, Herts.

Pansy and Viola Society, The North of England
Sec. F. C. Marshland, 2 Jubilee Mount, West Lillands, Brighouse, Yorks.

Pansy and Viola Association, The Scottish
Sec. Hugh Campbell, O.B.E., 960 Dumbarton Road, Dalmuir, Glasgow.

Pelargonium and Geranium Society, The British
Sec. W. E. Lake, 20 Northwood Road, Carshalton Beeches, Surrey.

Pteridological Society, The British
Sec. J. W. Dyce, 46 Sedley Rise, Loughton, Essex.

Rose Society, The Royal National
Sec. L. G. Turner, Chiswell Green Lane, St. Albans, Herts.

Royal Horticultural Society
Sec. John Hamer, M.B.E., B.A., Royal Horticultural Society's Offices, Vincent Square, S.W.1.

Royal Caledonian Horticultural Society
Sec. John Turnbull, D.S.O., D.F.C., C.A., Royal Caledonian Horticultural Society, 44 Melville Street, Edinburgh 3.

Saintpaulia and Houseplant Society
Sec. Mrs. E. A. Robbins, 296 Perth Road, Ilford, Essex.

Scottish Rock Garden Club
Sec. Mrs. L. C. Boyd-Harvey, Boonslie, Dirleton, East Lothian.

Sweet Pea Society, The National
Sec. R. J. Huntley, 431 Wokingham Road, Farley, Reading, Berks.

Vegetable Society, The National
Sec. 288 Northumberland Avenue, Welling, Kent.

FINDING LIST FOR WEEDKILLERS

All the herbicides in this list are first-class chemicals which have been approved by the Ministry of Agriculture and are available in small packs designed for use by amateur gardeners. In case of difficulty in obtaining any of them, manufacturers should be contacted.

The list may appear unnecessarily long but the pipe dream of multipurpose herbicides is not a reality and the extent and value of chemical weed controls are only obtained by using herbicides for their specific purposes; as such they constitute an efficient and economic method of eradicating unwanted plants of all sorts.

Trade names	Chemicals	Manufacturers	Type of action	Plants controlled	Notes and precauti
WEED KILLERS FOR USE ON TURF					
"Bugges 2,4-D", "Dicotox", "Shell Weed-kill"	2,4-D	Bugges Insecticides Ltd., London Rd., Sittingbourne, Kent. May and Baker Ltd., Dagenham, Essex Shell Chemical Co. Ltd., 15–17 Gt. Marlborough St., W.1.	Hormone growth regulator trans-located throughout the plant.	Many broad-leafed weeds and some perennial ones. Best hormone type for killing daisies, dan-delions and plan-tains.	Primarily for use lawns Beware of drift.
"Bugges M.C.P.A." "Weed-a-Lawn" and "Spot" (in powder form)	M.C.P.A.	Bugges Insecticides Ltd., London Rd., Sittingbourne, Kent. Pan Britannia In-dustries Ltd., Britannia House, Waltham Cross, Herts.	Hormone growth regulator trans-located throughout the plant.	Many broad-leafed weeds and some perennial ones. Best hormone type for killing creeping but-tercup. Useful against pearlwort with repeated ap-plications.	Primarily for use lawns Beware of drift; small areas powdered formula in puffer pack can used.
"Clovotox" "Lawn Clover Killer"	Mecoprop	May and Baker Ltd., Dagenham, Essex. Pan Britannia In-dustries Ltd., Britannia House, Waltham Cross, Herts.	Hormone growth regulator trans-located throughout the plant.	Best control for white-flowered clov-er, chickweeds and field woodrush. Use-ful against pearl-wort with repeated applications.	Primarily for use lawns Beware of drift.
Lawn sand "Velves Lawn Sand" "pbi Calomel Dust"	*See* T33(2).	Usually home made. Pan Britannia In-dustries Ltd., Britannia House. Waltham Cross, Herts.	Scorching of annual growth. Of herbi-cidal and manurial value, in most cases.	Invaluable against weeds resistant or semi-resistant to hormones, like pearl-wort, moss, veronica (speedwell), yellow-flowered clover, and yarrow.	*See* Lawns (T33(2)) detailed informat The use of calo dusts should be c fined to mosses; no manurial valu
WEEDKILLERS FOR GARDEN USE					
"Nova Soil Steriliser"	Cresylic Acid	The Murphy Chemi-cal Co. Ltd., Wheathampsted, St. Albans, Herts.	Contact herbicide.	For destruction of growth of annual weeds and top growth of peren-nials.	Particularly valua on asparagus b and where ann weeds have to controlled. Also u as a soil steriliant.
"Bugges Dalapon"	Dalapon	Bugges Insecticides Ltd., London Rd., Sittingbourne, Kent.	Translocated throughout the plant, killing vege-tation by move-ment from leaves to roots.	Annual grasses, couch grass, sedges, reeds, and bulrushes.	Delay planting for days after appli tion. May be u upon makers' structions as a *se lective* herbicide on as ragus, shrubber fruit gardens, etc.
"Weedol"	Diquat Salt	Plant Protection Ltd., Yalding, Kent.	Translocated throughout the plant but with scorching effect similar to contact herbicides.	Kills annual weeds and top growth of perennials. One of the few herbicides to give a good con-trol of ground elder. Selective only by ap-plication, i.e., kills all foliage it con-tacts.	Undoubtedly one the most valua and interesting he cides to be in duced. Inactiva upon contact w soil; no resi effects. Available small packs. Can stored from sea to season.
"Weedex"	Simazine	Fisons Horticultural Ltd., Harvest House, Felixstowe, Suffolk.	Soil acting, killing seedling vegetation by uptake through roots.	Controls germinating seeds of many weeds over a long period.	Apply when groun wet in early spring asparagus, app pears (not plu soft fruit, or mental trees, shrubs inclu roses. Slow acti
"Polybor-Chlorate"	Sodium Chlorate	Borax Consolidated Ltd., Borax House, Carlisle Place, S.W.1.	Translocated throughout the plant and soil act-ing.	Toxic in varying de-grees to all plants except mosses. The best chemical for killing tree stumps.	To a large ex superseded by o chemicals. Can used on paths, dri and vacant groun
"Boots Bram-ble, Brush-wood and Nettle Killer"	2,4,5-T	Boots Pure Drug Co. Ltd., Station Street, Nottingham.	Hormone growth regulator trans-located throughout the plant.	Special value in con-trol of woody plants like brambles, brush-wood, and ivy. Also good against nettles.	Beware of drift.

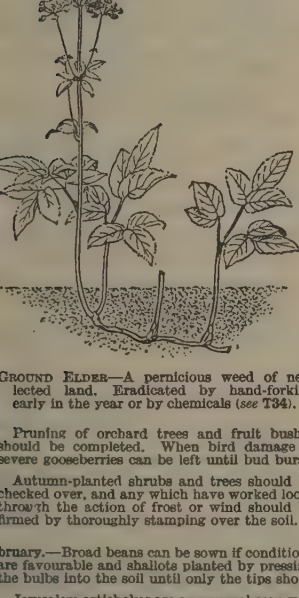
THE GARDEN CALENDAR.

nuary.—All digging should be finished this month. As the work is done, so generous applications of organic matter such as peat, compost, sewage sludge, leaf mould, animal manure, or a mixture of any of them, should be incorporated into the ground. On clay soils the physical condition can be improved by raking into the surface dressings of rough materials like screened ashes, road grit, or coarse sand.

Fork over ground between rows of fruit trees and in shrubberies and bury annual weeds; if land is not free of weeds in January it is unlikely to be so throughout the year.

A trench for runner beans can be made, the bottom forked over, a thick dressing of compost or kitchen waste added, and the soil replaced.

Rhubarb will require protection with compost or straw and early growth forced by covering with small tubs.



GROUND ELDER—A pernicious weed of neglected land. Eradicated by hand-forking early in the year or by chemicals (*see* T34).

Pruning of orchard trees and fruit bushes should be completed. When bird damage is severe gooseberries can be left until bud burst.

Autumn-planted shrubs and trees should be checked over, and any which have worked loose through the action of frost or wind should be firmed by thoroughly stamping over the soil.

bruary.—Broad beans can be sown if conditions are favourable and shallots planted by pressing the bulbs into the soil until only the tips show.

Jerusalem artichokes are an unusual crop well worth growing; plant tubers as early as possible to give a long season for maturity.

Parsnips should be lifted to check new growth and stored on the north side of a wall or fence.

"Seed" potatoes can be arranged in boxes and kept in a frost-proof shed; a light, airy position will encourage short, sturdy shoots.

Protective covering on half-hardy shrubs, like fuchsias and mimosa, should be removed as early as possible.

Herbaceous plants which do not over winter easily, such as delphiniums and gaillardias, may be planted at the end of the month.

Turf may be laid in February so that the grass can be established before the ground starts to dry out in the spring. Before laying, rake in a dressing of "National Growmore" at 1½ oz. per sq. yd. to encourage root action.

Vines under glass should still be kept as *cold* as possible to maintain the dormant period. As the buds swell the temperature can be higher, but ventilation must be increased if it reaches 45° Fahrenheit.

Fuchsias grown under glass should be pruned hard by cutting back all of last season's growth to within a bud or two of the old stems. Later, as new growth appears, take cuttings which will root easily in sand under a plastic bag.

Shrubby plants like the india-rubber plant and most pot plants grown indoors or under glass should be repotted or top dressed with fresh potting compost.

Early strawberries can be obtained by cloching rows at the beginning of the month.

March.—Sow round-seeded spinach and broad beans for a succession in cropping.

Brussels sprouts, cabbage, lettuce, leeks, onions, parsley, parsnips, peas, and radish should all be sown as the soil gradually warms up

Asparagus is easily raised from seed sown this month. Sow the seeds individually 1 in. apart and mark the rows by sowing a pinch or two of radish seed at intervals, as the asparagus is slow to germinate.

Onion sets can be planted as early as possible on well-manured ground.

Spring cabbage will respond in the spring to an application of nitrate of soda at 1 oz. per sq. yd.

Tomato seed may be sown in a warm greenhouse at the end of the month. It is a mistake to sow early in the year, as then seedlings get drawn and weak before it is time for planting outdoors.

Seed of half-hardy annuals, such as antirrhinums, China asters and *Phlox drummondii*, may all be sown in a greenhouse or frame. Remember the seed should only be covered with a sugaring of fine soil sufficient to "anchor" the seedlings and to sow thinly.

Hedges, and particularly evergreen sorts which have outgrown their stations, should be cut back, and this is the *best* month for doing so. Often drastic reduction is necessary, and such treatment will save endless, unnecessary work in trimming later on in the year. As an example, privet may be safely reduced to a width of 9 in. and a height of 4–5 ft.

Evergreen shrubs, like some daphnes, rhododendrons, and hollies, may be planted and—what is most important—kept moist until growing freely.

Over-grown lavender may be reduced in size by cutting back into old wood.

Lawns should be fed with fertilisers to encourage new, strong growth when the turf is damp.

As buds burst on roses, so pruning and manuring can be started.

Planting time for all fruit trees is nearly over, and should be completed without delay.

As buds burst on early planted raspberries, so the already shortened canes can be cut down to just above the lowest bud in growth; as further growth develops so the old stems can be shortened further until, finally, cut to ground level.

April.—Potato planting for an early crop is done this month using well-sprouted "seed." Protect from late frosts by covering the first shoots with earth and, if necessary, applying a coating of straw or sacking.

Onions raised under glass in boxes can be planted outdoors.

Watch for germination of asparagus seed; as the fern-like growths appear, hand weed the rows with great care and thin seedlings to 2–3 in. apart.

Hardy annuals can be sown outdoors when soil conditions are right; lightly cover and protect from birds. Half-hardy sorts must be grown-on in frames.

New stocks of carnations, chrysanthemums, and violas may be planted outdoors.

Transplant autumn-raised sweet peas to open garden early in the month.

Lawns may be sown as the soil warms up, and a good surface tilth can be obtained by raking; *prior* to sowing, make arrangements to protect the seed bed from birds by use of pea sticks, wire netting, strips of newspaper dipped into lime-wash, or "Glitterbangs" or a combination of these scarers.

Evergreen shrubs, like bamboos, hollies, and rhododendrons, should be planted and kept moist until well established.

Gladioli and montbretias can be planted in sunny positions where soil is in good heart.

Prune winter-flowering shrubs, such as winter jasmine and forsythia, by cutting off the old flowering stems.

Weeds will be appearing on garden paths and drives; establish an early and efficient control by watering with "Weedex."

Early planted fruit trees should be mulched with organic matter to conserve moisture in the soil.

May.—Brussels sprouts should be planted early in the month and also late potatoes. Watch out for blackfly on broad beans, as the first infestations are the important ones to deal with promptly.

Encourage growth on leafy vegetables, like lettuce and spinach, by a dressing of nitrate of soda at 1 oz. per sq. yd.

Towards the end of month plant out tomatoes, or in the first week if cloches are available.

Sow sweet corn and vegetable marrows in the open. Bedding plants and half-hardy annuals may all be planted outdoors.

Roses should be checked over for first signs of greenfly infestation; spray with nicotine if necessary.

Garden pools in need of cleaning should be dealt with thoroughly. At the same time water lilies may be lifted and divided when growth in the previous year was excessive.

Delphiniums now develop rapidly; for best results cut out thin shoots to leave five to seven strong growths to each plant. Stake and tie each one and encourage healthy growth by feeding with liquid animal manure or soot water on one or two occasions.

Faded blooms on azaleas, lilacs, and rhododendrons should be removed.

Agapanthuses and hydrangeas grown in tubs can be brought into a sunny position. If repotting has not been necessary remove top 2 in. of soil and replace with fresh compost. Encourage new growth with applications of liquid animal manure.

Window boxes should be repaired, filled with fresh compost, and replanted. Remember a generous layer of peat or leaf soil placed in the bottom will do much to conserve moisture.

Lawns will need attention, and broad-leaved weeds can be eliminated by treatment with hormone weed-killers.

Small greenhouses are liable to get very and plants suffer accordingly especially if sh of water: therefore keep staging and floors damped. Conversely, sharp falls in temp ture may be experienced and every day ventilators should be shut down in the afternoon in order to conserve the heat from sun.

June.—Plant cabbages, cauliflower, celery, r rows, and tomatoes.

Sow seed of garden swedes.

After thinning beet, carrots, onions, parsnips, feed with nitrate of soda at ½ oz. yd. run.

Asparagus raised from seed must be clear of weeds and watered thoroughly at least sign of being dry. Beds cropping in t third season should not be cut after June on old beds cutting may continue until the t week of June.

Sweet corn should be thinned and a sur dressing of compost applied.

Aubrietas now past their best should clipped back hard to the old stems, with a of shears.

Seed of delphiniums, hollyhocks, lupins, wallflowers may be sown.

Phloxes, especially if grown on light should be mulched with compost and wat when necessary.

Herbaceous plants of all sorts respond feeding if growth is below par; indivi species may be fed with soot water or beds given an application of sulphate of amm at 1 oz. per sq. yd., taking care to keep crystals off the foliage of plants.

Old flower heads on roses should be rem regularly by cutting back old flowering s to within 4 or 5 in. of the mature wood.

Raspberries and similar berries should mulched with compost or old manure encourage new growth.

Strawberries may be layered if the sto healthy and growth vigorous.

July.—Plant winter cabbage, leeks, sprou broccoli, and kales as ground becomes avail

Sow prickly spinach and turnips for aut and winter use.

Water celery, marrows, and runner bea first sign of dryness. If setting is poor, b should be sprayed vigorously with water a hose.

Shallots may be lifted and dried off as fo gradually yellows.

Carnations may be layered as sturdy y shoots develop; remove sufficient leave make a horizontal cut up the stem pa through a joint, and peg down.

Flag irises can be lifted and divided as flo ing finishes. After replanting, the t should be showing above ground but, neve less, firmly in the soil.

Wallflowers may be lined out in nursery To avoid sappy, lush growth do not plan rich soil. Where ground is acid water p with lime-water (a large handful to a gallo

Hydrangeas can be easily propagate July by cuttings of short flowerless sh These should be inserted in pots in a s compost and kept under a plastic bag or light until rooted.

Transplant into nursery rows, seedlin biennials and perennials sown earlier in year.

Order supplies of daffodils, hyacinths, and other bulbous plants for delivering in September. Stocks in good trade houses are often soon exhausted.

Late in the month hedges of beech, holly, hornbeam, and yew can be clipped.

ugust.—Runner beans are now in full bearing, and the pods should be gathered while still young, to encourage further croppings; often beans are picked much too old. Water and feed with nitro-chalk at 2 oz. per yd. run if necessary. If properly grown this is one of the most profitable of *all* crops.

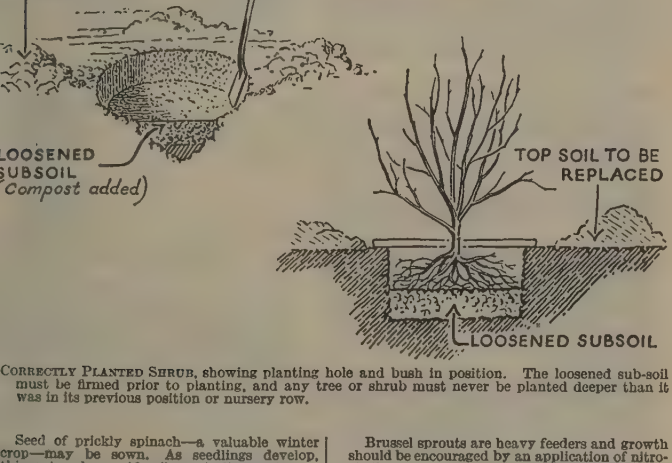
Marrows should also be gathered while still young and fresh; early development of seeds checks fruiting.

Strawberries layered in pots earlier in the year may be planted when the soil conditions are right. Use a well-manured site and plant at approved distances.

Raspberries and loganberries will now have finished cropping, and all the old fruiting canes may be cut out at ground level.

September.—Tomatoes can be gathered while still green and ripened easily and quickly by storing in open boxes, out of the direct sun, in a warm kitchen. Such a practice is better than putting the fruit in a dark, airless cupboard.

Ground recently cleared of onions and potatoes is admirable for planting out cabbages for spring cutting. Apart from removing any weeds, no preparation is desirable.



CORRECTLY PLANTED SHRUB, showing planting hole and bush in position. The loosened sub-soil must be firmed prior to planting, and any tree or shrub must never be planted deeper than it was in its previous position or nursery row.

Seed of prickly spinach—a valuable winter crop—may be sown. As seedlings develop, thin out and on acid soils apply lime-water.

Tomatoes should be sprayed with "Bouisol" at fortnightly intervals to prevent potato blight.

Winter greens, if not already planted, should be put in as soon as possible.

Pelargoniums ("Geraniums") should be propagated by cuttings taken throughout the month as young, short side-shoots develop. Rooting soon starts if the cuttings are inserted in sand or a mixture of sand and peat.

Border carnations may be layered; encourage rooting by not allowing the plants to suffer from a lack of water.

Madonna lilies may be planted this month in an open position where they will not be disturbed.

Flowering shrubs of a wide range may be propagated in August. Short side-shoots of the current season's growth should be taken off with a heel when the wood is still young but starting to harden at the base. Insert in sand and cover with a plastic bag.

Grass seed is best sown this month whenever the soil is moist but not wet, as in the notes for April. Before sowing, any perennial weeds must be removed by hand forking.

Brussel sprouts are heavy feeders and growth should be encouraged by an application of nitro-chalk at 1 oz. per sq. yd. early in the month.

Carnation layers will now be rooted and the young plants may be severed from the parents and transferred to their flowering positions.

Crocuses, daffodils, and snowdrops are often planted too late; September is the time for the job. Similarly, these, together with hyacinths, may all be planted in bowls for indoor decoration before the end of the month.

Lavender bushes can be trimmed when the flowers fade; do not, however, trim or cut back in any way the old stems or foliage.

Grass seed not sown last month should be put in without delay.

Roses of nearly every sort can be propagated by inserting cuttings 8–10 in. long in a shallow trench outdoors. A sprinkling of sand should be put in the bottom of the trench and the cuttings firmed well.

Brown rot is often prevalent on fruit. There is no remedy for the disease, and brown, rotten fruit on apple and other trees should be picked off and burnt.

October.—Jerusalem artichokes are safe left in the ground, but the stems should be cut down.

If a regular supply is wanted, then a store of tubers may be lifted to ensure against hard frost.

Parsnips may, similarly, be left in the ground until needed.

Asparagus stems should be cut down before the seeds drop. If "fern" is cut during the summer for indoor decoration, subsequent cropping is affected.

Lettuce for early cutting next spring should be sown, late in the month, under cloches.

Virgin ground which is to be taken into cultivation should be dug as soon as possible in order that it may be exposed to a *full* season of winter frosts. There is no doubt that the maximum value in digging virgin land can only be had if the work is completed well before Christmas.

Evergreen shrubs should be planted before the weather turns severely cold.

Lily-of-the-valley will respond to a top dressing of old animal manure or an application of bone meal at 2 oz. per sq. yd. followed by a mulch of leaf soil.

Clematis grown in pots may be planted in their permanent positions.

Lilies of various sorts can be planted early in the month.

Gladioli should be lifted, cleaned, and stored in a dry, frost-proof shed.

Polyanthuses and all sorts of primroses may be planted in moist, rich soil for flowering in the spring.

Sweet Williams and pansies may be transferred from nursery rows to their flowering positions.

Wallflowers should be planted without delay, firming the plants well. Forget-me-nots and daffodils may be used in conjunction with them and planted at the same time.

Most plants grown indoors have been watered freely during the summer; from now on care must be taken in applying water, as soil only dries out slowly in winter, and growth has virtually stopped.

Bulbs in bowls must be kept as cold as possible, and up to early November not more than about ½ in. of growth should be showing. Damp the peat as it shows signs of drying out.

Black and red currants and gooseberries may all be propagated by cuttings.

November.—Runner beans can be cleared and the haulms used for compost; the old roots can be left in the ground and later dug-in. If the sticks are pulled up early and stored they will last for some years.

Broad beans may be sown outdoors in districts where they are known to succeed; an allowance for losses should be made by sowing 3 in. apart.

Asparagus responds well to a top dressing of animal manure or compost; if supplies are short, aim to apply once in three years.

Lettuce sown last month under cloches can be transplanted and, under wide barn cloches, three rows can be grown easily for cutting in the spring. Slugs may cause serious losses, so water with "Slugit" at planting time and keep a few spare seedlings to fill any gaps.

Tulips may be planted throughout November.

Heaths and heathers of all sorts can be planted in peaty soils. Large clumps may be split up and replanted.

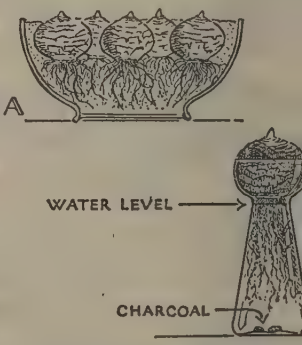
Roses and all deciduous shrubs and trees, including fruit trees of all sorts, should be planted as soon as possible. Always firm soil well, but do not plant too deeply.

Where necessary, herbaceous borders ca replanted. Large clumps of perennials ca split up and the strong pieces from outsi the clump replanted; the centre of the c should be discarded.

Continue to keep indoor bulbs as cold as sible. By the second week in Nover growth should be about an inch high. Tov the end of the month, transfer to a cool, position.

Throughout the winter continue diggin incorporating organic matter like com spent hops, and coffee grounds.

Vines grown in a cold greenhouse shou given full ventilation night and day. leaf fall cut back annual growth to one b



BULBS INDOORS—Note strong root dev ment before leaves appear. This facto only be brought about by early plantin September notes). In both bowl (A glass (B) a little bonfire charcoal is nece for healthy growth.

December.—Decaying leaves on winter should be removed to give free circulation around the plants.

Bird damage may be prevalent on s cabbages because of pigeons. In serious it is worthwhile to erect fish netting.

When frost makes cultivations impos pruning of fruit trees should be done. The exception may be red currants and goosebe because in districts where bird damage is se any pruning is best left until the spring.

Deciduous hedges of beech, hawthorn, the like can all be cut back hard where the p have got out of hand, with a view to red work of trimming during the growing seas

Well-berried holly is always in demand a variety of regular fruiting habit to fulf requirement is *Ilex aquifolium* 'Pyramidal

For those wanting mistletoe, the seed sh be planted on apple trees in the spring—n December.

Early in the month, hyacinths can be bro into full light and warmth for Christmas flo ing. If growth is a little stunted cover p with a sheet of newspaper and give warmth; if growth is poor look to the culti not the supplier.

Christmas trees to be brought indoors in should be thoroughly watered first, to chec needles falling through lack of moisture in stuffy rooms.

CULTIVATION OF INDOOR PLANTS

house plant is one which can be grown per-nently for decoration indoors. Such plants uld not be confused with orchids and the like wn indoors, for these are really warm green-se plants or denizens of Scandinavian or erican houses where the temperature and air ditions may be automatically controlled. Re-tably the normal British home is often cold draughty and has a high temperature in the ning and a low one at night. This is far from sfactory and confines the cultivator to selection plants tolerant of such factors.

Cultural Conditions.—Ideally the temperature uld be kept as constant as possible and in cold ather tender plants grown on window ledges best moved nightly into the centre of the room avoid damage by frost.

Linked with temperature is the question of midity. This factor is important, as plants pond well to a moist atmosphere. To obtain egree of dampness pots can be sunk in peat or od on a layer of gravel which can be kept ist.

Other factors adversely affecting the health of nts are gas fumes and draughts. Geraniums d African violets are particularly sensitive to gas d it will cause the Jerusalem cherry (*Solanum psicastrum*) to shed its leaves and berries quickly.

Feeding and Potting.—However well a plant has en grown, the turning point culturally is in its potting; from this juncture it either thrives or clines. A good potting mixture can be made up home with:

7 parts in bulk of fresh soil
3 parts in bulk of peat or leaf soil
2 parts in bulk of gritty sand or fine grit

To this mixture can be added a balanced ferti-r available from any good sundriesman. If it not added then most plants should be fed during e growing season at about fortnightly intervals epending on the particular plant) with a pro-etary liquid fertiliser or, best of all, with a ute solution of liquid cow manure. Indeed, the lue of feeding, particularly with rich organic nure, cannot be over-emphasised.

Normally a plant will grow in the same soil for ee or four years. After this repotting should carried out. When repotting is not necessary, w growth can be encouraged by removing the p inch of soil and top dressing with fresh com-st. Both repotting and top dressing are best ne before growth starts in the spring.

Health of Indoor Plants.—The number of pests d diseases affecting indoor plants is small and owers should remember that the majority of oubles are due to faulty cultivation or lack of nurial treatment.

Occasionally aphids (green or black flies) may seen on young growth. These can be destroyed wiping the shoots with water containing a le detergent and repeating the treatment as cessary. On ivies and palms, in particular, can found a brown waxy scale. Underneath the otective scale shelters a sap-sucking insect ich can be removed by hand.

Another insect occasionally seen is the mealy g, an aphid which is surrounded by a pro-nent white, woolly coating. Control in this se is easily established by dabbing the indi-luals with a little methylated spirits.

Basal rotting of flower stems and leaves, to be en on cyclamen and African violets, for instance, due to a fungal infection. It can be avoided by ention to correct watering and temperature. kewise, premature yellowing of leaves and leaf opping is primarily a cultural trouble brought out by excessive cold, draughts, gas fumes, er-watering, perhaps over-feeding, or a combi-tion of some of these factors.

Selection of Plants.—For ease of reference the lowing list includes plants which can be grown permanent features indoors, and florists' plants e cyclamen and primulas. These latter sorts e normally purchased in bloom and discarded hen flowering finishes.

Azalea.—Varieties in a wide range of colours are sold in late autumn and early winter. The plants are imported from Belgium and forced by English nurserymen. Azaleas need generous watering preferably by immersion in order to soak the root ball thoroughly. After flowering, plants may be stood out of doors in the summer and kept moist, but normally do not flower freely again for two or three years.

Begonia.—An enormous genus of plants of world-wide distribution, many being suitable for indoor cultivation. The large-flowered sorts known as tuberous begonias are potted in the early spring and kept in a temperature of 65–70° F. Once growth starts, water freely and feed fort-nightly. After flowering gradually withhold water and then store the corms until the following spring. Bud drop and yellowing of the leaves is usually due to faulty watering or draughts.

Campanula isophylla (Harebell).—A charming blue-flowered plant with a long flowering period. Easily grown in cool conditions and its pendulous habit makes it useful for a basket. After flower-ing, remove dead flower heads and trim straggly shoots. There is a good white form, 'Alba.'

Cacti.—Innumerable sorts are used as house plants. In the main, all should be grown in a sandy, gritty soil. Water may be given freely in the summer but withheld in winter except to pre-vent the soil drying out. Two cacti which will flower freely and are particularly worthy of culti-vation are *Aporocactus flagelliformis*, the rat's tail cactus, and *Epiphyllum ackermanii*. The latter has long, leaf-like, flattish stems and brilliant large flowers which can be encouraged by feeding with cow manure. It does best when its roots are restricted in a small pot.

Mention must be made of the old-fashioned Christmas cactus, *Schlumbergera bridgesii*, as a great favourite, but an infinitely more exciting one of similar ilk is *Rhipsalidopsis gaertneri* with bright-red flowers. Here again both sorts respond to regular watering and manurial treatment when the buds show until the flowers wither.

Chlorophytum elatum.—One of the most popular house plants by reason of its ease of culture. It is most attractive with its green leaves boldly striped with cream-coloured bands. This plant is tolerant of adverse conditions but does need feeding in the summer and regular repotting. A good one for beginners.

Christmas or Winter Cherry.—*See* Solanum capsicastrum.

Cineraria.—Normally plants are bought in flower in the winter. They require cool condi-tions, good light, but not full sun, and care in watering. Numerous varieties have been raised with their daisy-like flowers ranging in colour from white to red and violet blue. In nature the cine-raria is a perennial, but the hybrids are not worth keeping once flowering is over.

Crassula.—Shrubby members of this genus make fine house plants, growing well in light soil in full sun. Particularly valuable are *C. lactea*—which has white flowers and large succulent spoon-shaped foliage—and *C. falcata* with red and yellow flowers.

Cyclamen.—Indisputably a really well-grown cyclamen is the hallmark of a good cultivator. When buying a plant choose one which has been grown slowly in cool conditions and therefore has stiff, self-supporting stems. Failures are usually due to faulty watering. Rules cannot be formu-lated for correct watering, but as a generalisation the pot should be filled to the brim about once a week (*see* Health of Indoor Plants).

When annual growth dies, water can be withheld to a large extent and the corm saved for the next year. It must be remembered however that while corms can be grown on for 15–20 years the best results are always obtained in the first season. Mr. Allan G. Langdon, an expert in growing cyclamen, has written an excellent account of the plant in the R.H.S. *Journal* (October, 1948) pp. 322–7 which may be consulted through most public libraries.

Ferns.—While many will thrive indoors, sorts like the maidenhair fern require more atmospheric moisture than is desirable in a house. One of the best is the sword fern. Its long, graceful stems will reach 3 ft. in length and it is tolerant of neglect. It is this kind that is utilised by Superintendents of Parks for decoration at civic functions.

The one used by florists for button holes is the asparagus fern. This is another of easy culture but strong annual growth should be built up by feeding in the summer.

Ficus.—The species most often seen is the india-rubber plant (*F. elastica* ' Decora') with its broad, leathery, shiny leaves. Often proves difficult to grow and leaf drop and yellowing may be caused through cold, draughts, or gas fumes. Found at its best in centrally-heated houses.

Geranium.—*See* Pelargonium.

Gloxinia.—Although often used to good effect for house decoration, the best specimens are to be found in the moist atmosphere of warm greenhouses. When grown indoors keep the plants moist in a warm room but shaded from direct sun. To encourage a succession of flowers feed fortnightly with liquid manure.

Strange as it may seem all of the lovely forms in a wide range of colours have been selected from a single Brazilian species.

Helxine soleirolli (Mind-your-own-business).—Appropriately named from its habit of thriving where it is not wanted. Makes a pleasant mass of thin green trailing stems. Should be kept always on the wet side.

Indiarubber plant.—*See* Ficus.

Ivy.—Known botanically as *Hedera*, ivies make useful indoor plants, showing an interesting range of colour, shape, and size in their foliage. A related plant raised in France is *Fatshedera lizei*. All need a damp, leafy soil and the foliage should be sprayed regularly, preferably with water from a garden hose. Scale insects will affect development (*see* Health of Indoor Plants).

Monstera deliciosa.—A striking plant for a warm room with large, deeply-cut leaves and long, thick aerial roots many of which do not reach ground level. Often seen as a prominent ornamental feature in large stores and, seemingly, as an inevitable decor for television plays. It requires a leafy soil, generous watering, and regular sponging of the foliage.

Palms.—Like the aspidistra, the palm is considered a relic of Victorianism and on such slender evidence is condemned. Notwithstanding, palms make fine decorative plants. Great care must be taken when repotting not to damage the thick roots, and for a number of years it is only necessary to top dress if feeding is done during the summer. Spray the foliage regularly and keep a watch for the appearance of scale insects (*see* Health of Indoor Plants).

Pelargonium (Geranium).—Both ease of culture and beauty are found in this plant and its infinite varieties. Some, like 'Mrs. Cox,' have n coloured leaves and are well worth seekin nurserymen's lists. In growing the com geranium it is often overlooked that the bes sults are from young plants; to this end ther cuttings should be rooted in July or Augu replace old, woody stock.

Philodendron.—Mostly climbing plants a aerial roots and fine foliage. They require a soil, regular watering and spraying of the fo and a warm winter temperature.

Pick-a-back Plant.—*See* Tolmiea menziesii

Primula.—At Christmas time numerous v ies of primulas are offered for sale and make presents, for with care they have a long seas flowering. Further, all are of easy culture a top dressed and fed, can be grown on for a or two.

The three species grown have their orig China and varieties of one, *Primula obconica*, cause a rash on those susceptible to it.

Saintpaulia.—The African violet is a cha dwarf plant with hairy leaves and attractive and double flowers usually violet blue. It *difficult* plant to grow well as it thrives in a perature upwards of 65° F. and a wet atmos Rotting of the leaves is usually due to moisture in the soil when the temperature i Draughts, too much sunlight, and gas fire affect the health of the plant.

Saxifraga sarmentosa.—A small plant of d ing habit tolerant of cold rooms and of ne Its reddish leaves and pink flowers make it attractive. Should be kept moist.

Solanum capsicastrum.—Commonly know winter, Christmas, or Jerusalem cherry this is a native of Maderia and is grown for its br scarlet berries. If grown in a cool temper watered freely, and fed with liquid m occasionally it has a long season. But it tolerant of gas fumes which quickly caus leaves and berries to drop. The winter can be grown on from year to year, but it i to replenish the stock annually.

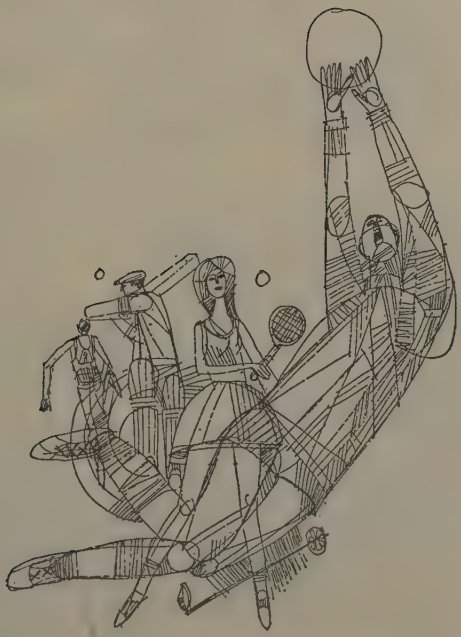
Tolmiea menziesii.—Although of no distin beauty, the pick-a-back plant is often grow doors as it is tolerant of the worst of cond Young plants develop on the hairy, oval l hence its common name. Probably it was duced from British Columbia by the Scottish collector, Dr. Archibald Menzies. Leav tolmiea root easily in water.

Tradescantia.—This trailing plant has va ted leaves and is the most commonly grown indoor pants. When stems with green develop these should be nipped out. To en age well-marked variegations the trades should be grown in full sun.

Vines.—Two of these are particularly va as climbing plants; *Cissus antarctica*, a nat Australia and *Rhoicissus rhomboidea*, a Na plant which does not appear to have been to any extent until after the Second World Young growth must be encouraged durin summer by keeping the foliage free of occasionally feeding and watering regularly

Zebrina pendula.—Related closely to *T cantia* and often their nomenclature is con Like its relative it is difficult to kill. Its have a pleasing metallic lustre and beneath shade of blood-purple.

GAMES & RECREATIONS



GAMES AND RECREATIONS

PEOPLE have always been fond of playing games and of thinking out ways of spending their leisure and of celebrating special occasions. The result is a long history of games, recreations, and cus some of which are described in this section. The arrangement is alphabetical.

One problem that confronts those keen to try some game or recreation is how to set about it many cases, the simplest way of finding out what facilities exist in a particular area is to enquir local newspaper office, which will have particulars of all sports clubs, dramatic societies, and recreational bodies in the area. A few addresses that might be useful to those with certain spect interests appear at the appropriate places in the text, and a valuable source of helpful informati many games and recreations is the Central Council of Physical Recreation, which has English, Sco Welsh, and Northern Irish addresses as follows: England, 6 Bedford Square, London, W.C.1; land, 4 Queensferry Street, Edinburgh, 2; Wales, 18 Windsor Place, Cardiff; and Northern Ir 45 Arthur Street, Belfast. Those keen on touring the country at moderate cost might apprecia services provided by the Youth Hostels Association, which has addresses as follows: England Wales, Trevelyan House, St. Albans, Herts, with a London office at 29 John Adam Street, W Scotland, 7 Bruntsfield Crescent, Edinburgh, 10; Northern Ireland, 28 Bedford Street, Belfast the Irish Republic, 39 Mountjoy Square, Dublin.

American Football.

American Football is played eleven-aside on a pitch marked by a line across it every 5 yards, and with goals and a ball resembling those used in Rugby Football (*q.v.*), though the ball is smaller. Scoring is by "touchdowns," which are like Rugby tries, but count six; goals after touchdowns, which count one; field goals during play, which count three; and "safeties," which give the attacking side two points if the defenders carry the ball over their own goal-line and touch it down. The ball is advanced by carrying it, forward passing, and kicking. The game consists of a series of "plays" or "downs," the ball becoming dead when the ball-carrier is tackled. A team must advance 10 yards in four downs or give up the ball to their opponents. Players can run ahead of the ball-carrier to protect him by "blocking" opponents. Penalties take the form of distance, usually 5 or 15 yards, lost. A game lasts 60 minutes, divided into four 15-minute quarters.

Angling.

Angling, which is catching fish with rod, line, and hook, goes back to beyond the beginning of history, for it was known to the Greeks and Romans. It is now a recreation, for, though the catch may subsequently be cooked, it is not primarily fishing for the pot. It has its competitive side, with competitions offering prizes for the biggest catch, and there are angling clubs, but many people prefer to use it as a recreation to be enjoyed alone in quiet surroundings. It is actually not so much a recreation as many recreations, for fishing can take place in the sea, rivers, lakes, ponds, and even canals, and there are several entirely different kinds of angling. The most obvious divisions are fresh-water fishing, including coarse and fly-fishing, and sea angling, including fishing from piers and the shore and big-game fishing.

The biggest branch of angling is fresh-water fishing for general or "coarse" fish, which are so called to distinguish them from "game" fish like salmon. Coarse fishing is bait fishing, or, in the case of pike, spinning, groundbait also being thrown in before and during fishing. It covers many varieties of fish, and the bag may be a very mixed one. Certain fish, of course, are known to frequent certain localities or types of locality, but, though the angler may know exactly the kind of fish he is after, he rarely knows if his catch will consist entirely of that kind of fish, or even if it will include any of that kind. Coarse fish do not generally make good eating.

Fly-fishing for salmon and trout differ widely from coarse fishing, and from each other. As the name implies, artificial flies are used, but those used for trout are quite different from those that attract salmon. In the case of trout, a fly is to resemble a real insect as closely as possible with salmon, this is not necessary. S rarely, if ever, feed in fresh water, and, wh that type of water, they are usually irri They will dart wildly at any objects that a their attention, so salmon flies are simply objects designed to draw them on. Fly-fish rather an expensive sport, for it means beats on private water. In both coarse an fishing the angler would be well advised to out of sight of the quarry as much as possible

Sea angling is now the most competitive of angling, with sea-angling festivals and petitions plentiful during the holiday season has what might be called its equivalent fishing with feathers, which attract several of fish.

Big-game fishing takes place from a launch, which is not towed by the hooked fis follows it, so that the ensuing fight is betwee and fish, and not between the fish and the weight of the boat. Such a fight could last hours, and it is never certain that the angl win it. Tunny is the only big game found British coasts.

Archery. *See* Old English Games and Custo

Association Football.

Games that may have resembled football played by very ancient races, and games certainly were football of a kind were pla the England of several centuries ago, bu Association Football that is the most popular in Britain, and perhaps the world, to-day h origins in the games played at English Schools in the days before sport became orga

It was not surprising that some of thos had played football of one kind or anot school should want to go on playing afte left, but, before they could do so, it was nec to work out a set of rules that would be unive understood and accepted. Meetings were c ised by those interested, and, as the unive were natural meeting-places for boys from schools, it was there, particularly Camb that these took place.

It was soon evident that there was a difference of opinion between those who w handling permitted and those who opposed The rival factions proved irreconcilable, s went their separate ways. The handling en asts based their rules on those in force at School, and thus pioneered Rugby Football Those who felt that football should be primarily with the foot brought into bei game that was to take its name from th sociation that was formed, in 1863, to gov

d became Association Football, often called the abbreviation, "Soccer."

Soccer is played with a round, leather-covered ll weighing from 14 to 16 ounces, and with a cumference of from 27 to 28 inches, on a pitch arked out as in the accompanying diagram. It played eleven-aside, the positions being goal-eper; right and left full-backs; right, centre, d left half-backs; and five forwards, playing at tside-right, inside-right, centre-forward, inside-t, and outside-left. The object is to score als by putting the ball between uprights yards apart and under a crossbar 8 feet high. e ball is advanced by kicking or heading, but ly the goalkeeper when in his own penalty area y handle it, and he may not carry it. A game ts for 90 minutes, divided into two halves.

The game is started by a kick-off from the ntre, with all the opposing players outside the ntre circle and in their own half. The ball ust travel at least its own circumference into the ponents' half, and the kicker may not play it ain until someone else has done so. The right to k-off is decided by a toss that gives the winner e option of kicking or choosing which goal he ll defend. Ends are changed at half-time, after hich the ball is kicked-off by the side that did t do so at the start. The game is restarted in is way after each goal, the non-scorers kicking-.

If the ball crosses the touch-line it is thrown in a player of the side that did not put it out, the row being two-handed. If it crosses the goal-e wide of the goal it is kicked-off by a defender om the 6-yards line if the attackers were respons-e, and by an attacker from the intersection of e goal-line and the touch-line if the defenders re responsible.

Infringements are penalised by free kicks, which ay be "direct" or "indirect." Direct free icks, from which a goal may be scored, follow liberate infringements, indirect free kicks, from hich a goal cannot be scored, being for more chnical offences. Offences by defenders in the nalty area are generally penalised by a penalty ck, which is a shot from a spot 12 yards out from e centre of the goal, with only the kicker and e goalkeeper in the penalty area, and the goal-eper barred from moving until the ball has en kicked. However, certain offences in the nalty area, such as carrying by the goalkeeper d obstruction, are penalised only by an indirect e kick.

A player is "offside"—called "sneaking" in e school games from which the rule came—if he nearer the opponents' goal-line than is the ball less there are two opponents between him a d e goal-line, or unless the ball was last played b- opponent. He cannot, however, be offside in his own half, from a corner kick, or from a throw-in. If a player in an offside position interferes with the game, a free kick is awarded.

A game is controlled by a referee, who has the assistance of two linesmen. These may signal infringements, but the referee is not bound to act on such signals.

In Britain, soccer is a winter game, the season lasting from August until May, though, in Scotland, it continues even during the short summer season in the form of five-aside football, known as the "short" game. British soccer is highly organised, ranging from the fully professional Football League of four divisions and the equivalent, though slightly smaller, Scottish League through minor professional leagues to amateur leagues. There are also many cup competitions, from the Football Association Challenge Cup and the Scottish Cup downwards.

The game has also spread almost all over the world, being extraordinarily popular all over Europe and in South America, and played to some extent in the United States, Canada, South Africa, Australia, and other areas. There is a World Cup competition that is played for every four years, a European Nations Cup, played for every two years, and an annual European Champion Clubs Cup competition played for by the top club of almost every European country. Soccer is also included in the Olympic Games.

Athletics.

The sport of Athletics, which includes running, walking, jumping, and throwing, is probably the most natural of all sports, and certainly one of the oldest.

Modern Athletics can be said to have begun in 1849, when the Royal Military Academy instituted a meeting that was followed by a similar meeting at Exeter College, Oxford, and, subsequently, at other Oxford and Cambridge Colleges. The Civil Service were also early in the field; and the first athletic club was the Mincing Lane Athletic Club, now the London Athletic Club. There was also the Amateur Athletic Club, which organised an annual championship meeting, and acted as a governing body for both athletics and amateur boxing.

In 1880 the Amateur Athletic Association was formed as a governing body. Other countries, particularly the United States, took to the sports and in 1896 the first modern Olympic Games were held at Athens. Other international meetings and matches followed, and championships and competitions of all standards were started in many countries. Women came into the sport in the early 1920s, and were included in the Olympic Games in 1928. There is now a long list of inter-

nationally agreed standard events, including distances measured in yards and miles, and also their metric equivalents; and including also a major all-round test, the ten-event Decathlon.

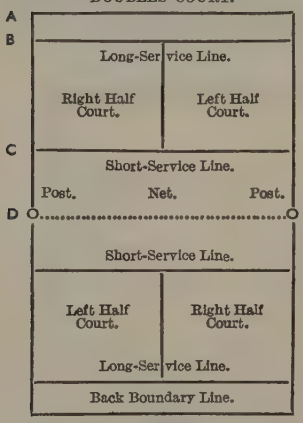
The longest strictly standard distances are the Marathon of 26 miles 385 yards for runners, and 50,000 metres for walkers, but there are regularly held longer events. For runners, the longest annual race is between Durban and Maritzburg, about 55 miles, the longest in Britain being from London to Brighton, about 53 miles; but there are occasional 100-mile and 24-hour events. For walkers, there are annual 100-mile races and fairly regular 24-hour ones.

The Marathon commemorates the run of the courier Pheidippides from the battlefield at Marathon to Athens, carrying the news of victory over the Persians (490 B.C.). This run covered about 25 miles but the distance was standardised at 26 miles 385 yards in the 1908 Olympic Marathon from Windsor to the White City, London. All Marathons commemorate the Battle of Marathon, but the oldest annual Marathon, the Boston Marathon, also commemorates the Battle of Lexington (the first battle of the American Revolution), and, more particularly, the ride by Paul Revere that preceded it.

Cross-Country. Athletics is mainly a summer sport, but in cross-country running it has an extremely popular winter branch.

Cross-country originated in the traditional runs at various English Public Schools, particularly Rugby and Shrewsbury; and came into wider prominence when it was adopted by the Thames Rowing Club as winter training. It is still used as training by many sportsmen of all kinds, but it is now also a thriving competitive sport in its own right. There is an International Championship, but this is not yet fully representative, being virtually confined to Western European nations. Major cross-country championships are over courses of 9 or 10 miles.

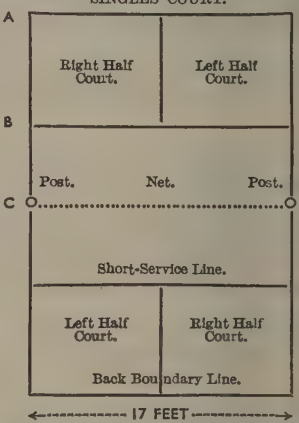
DOUBLES COURT.



NOTE.—If it is practicable place the posts on the side boundary lines; failing this, place them at any distance not more than 2 ft. outside these lines.

A to B 2 ft. 6 in. A to C 15 ft. 6 in.
A to D 22 ft.

SINGLES COURT.



NOTES.—Place the posts on the bounda lines or not more than 2 ft. outside the lines.

The back boundary lines become the lon service lines.

A to B 15 ft. 6 in. B to C 6 ft. 6 in.

Top of net 5 ft. from ground at centre and 5 ft. 1 in. at posts.

Diagram of Ground as marked out for Badminton.

Australian Rules Football.

Australian Rules Football is played 18 aside large oval grounds. At each end, there are posts seven yards apart; and scoring, whic high, is by goals, counting six points, when ball is kicked between the two inner posts, behinds, counting one point, when it is ki between the outer ones. The ball resembl Rugby ball, but is less pointed. Players must run more than 10 yards with the ball wit bouncing it or touching it on the ground. ball must not be thrown, but it can be passe holding it with one hand and punching it with other, or by kicking. Players in possession be tackled between the shoulder and the kne charged. There is no offside and no scrumma A game consists of four 25-minute quarters. game has existed since 1858, and is played t practical exclusion of all other forms of footb the southern half of Australia and in We Australia. There are over 3,000 clubs.

Badminton.

Badminton might be described as an in version of Lawn Tennis (*q.v*) in that it is pl over a net, and can consist of either singl doubles. There, however, the resemb ceases. Only the serving side can score. I server wins the rally one point is scored; loses the next player serves. A game is wo the side first making 15 points. Three g make a set. The shuttlecock or "bird" is a cork hemisphere in which feathers are fixed. shots are volleys.

Bandy. *See* Skating.

Baseball.

The invention of Baseball, a summer played from April until October, and the nat

ne of the United States, is generally credited to Army officer, its origins being old country mes called "One Old Cat" and "Two Old Cat." Teams are nine-aside, and bat and field in turn. e main part of the ground, the "diamond," has base," marked by a sack, at each corner, the es from sack to sack being the "base paths." e base is "home," and there the batter stands, a square of rubber on the ground, called the late." The base forward and to the right of a ht-handed batter is "first," the one straight ead of him is "second," and the one forward d to his left is "third," the distance from one e to the next being 30 yards. 20 yards out aight in front of the plate is the pitcher's ound." The lines from home to first and from ne to third are continued beyond these bases, d are the "foul lines."

t is the object of the batting side, using a bat ich resembles a long, heavy Indian club with ich to hit a hard, white ball weighing 5 ounces, score runs, one being scored each time a player npletes a circuit of the bases, not necessarily m one hit. When a batter leaves the plate, ner "out" or to proceed along the base paths, next man comes in, the team's innings lasting il three men are out. Nine such innings nplete the game, and, in each innings, the ting side carries on at the point in the batting er reached in the previous innings. There is toss for first innings, the visiting side always ting first.

The pitched ball reaches the batter without ching the ground, and, if not hit, it should pass r the plate between the batter's shoulders and es. If it does so, it is a "strike," and three h strikes dismiss the batter. If it does not, it , strike only if the batter swings at it; other- e it is a "ball," and four balls give the batter ree passage to first base, called a "walk." batter also walks if he is hit by a pitched ball. her ways in which the batter can be dismissed by being caught, and by being "put out" ile on the base paths by failing to reach the e to which he is running before the ball. nen an out is made, the ball does not become ead." If there is more than one runner on the e paths, then, if the ball can be relayed quickly ugh, two, or even three, men can be put out on same "play."

f the batter hits fairly, he must run, but, to be , the hit must be in front of him and between foul lines. A "foul hit" counts as a strike inst him, except that the third strike, which nally dismisses him, must be a clean one across plate. If a foul is caught, he is out.

The fielding side is divided into three sections, "battery," the "infield," and the "outfield." e battery consists of the pitcher and the cher, who stands behind the plate and gives nals indicating the kind of ball he thinks the cher should deliver: for, though the pitched l does not touch the ground, pitchers can duce a wide variety of deliveries, including ious kinds of curve. The infield consists of first baseman, at or near first; the second eman, between first and second; the short- p, between second and third; and the third eman, at or near third. The outfield covers ground beyond the infield, the three remain- fielders taking the right, centre, and left ions of it. Catchers wear a large glove on the -throwing hand, a mask, a chest protector, l leg-guards. All the other fielders wear a ve on the non-throwing hand, the first base- n's being larger than the others. The batter ars no protective gear.

ubstitutes are permitted, pitchers frequently ng changed if they are being hit, and "pinch ers" being sent in instead of weak batters if a is desperately needed. If this happens, the n replaced, often the pitcher, cannot return en his side fields again, though his field replace- nt need not be the man who batted for him.

s with Cricket (*q.v.*) batting averages are orded, these being calculated by dividing the nber of times at bat into the number of hits. average of 0·400, referred to as "four hundred," uld be exceptionally good. "Hits" mean safe hits on which the batter achieved one or more bases without giving a chance. If he reaches base because a catch was dropped or a ball mis-fielded, he plays on from there in the usual way, but is not credited with a hit. Pitchers are graded according to the number of games won and lost. Recorded fielding statistics include each man's "put outs," "assists," which are throws from which a team-mate made a put out, and "errors."

In the United States there are clubs and leagues of all standards, from professionals of various classes through semi-professionals to amateurs, called "sandlotters," and boys. The top class of all consists of two major leagues, the National and the American, each with eight clubs. The champions of these two leagues meet in a best-of-seven-games series for the "Championship of the World," always known as the World Series.

Baseball is also the chief summer game of Canada, and it is quite widely played in some other countries, including Australia, Britain, and Japan.

Softball. Similar to Baseball is Softball, which is popular in the United States with girls as well as men, and which was demonstrated in Britain during the War by American and Canadian servicemen. The ball is not particularly soft, but it is larger than a baseball, and pitching is under-arm. Distances between bases, and between the plate and the mound, are shorter than in the parent game.

Basketball.

Basketball was invented by an American Y.M.C.A. official at Springfield, Massachusetts, as a winter team game that could be played indoors. It can be played in almost any gymnasium or hall, and it can also be played outdoors on an asphalt court. In America it is played by teams of all standards from schoolboys to professionals, and it is watched by more spectators than any other game. It has also spread to almost as many other countries as has Association Football (*q.v.*), and it is included in the Olympic Games. It has been established for some years in Britain, where it has been encouraged by the Services and the Y.M.C.A.

Basketball is played five-aside, substitutes being permitted, with a ball resembling that used in Association Football, and goals consisting of posts that have iron rings with short nets attached to them and backboards. It is purely a handling game, and the ball is advanced by dribbling, which means bouncing, and by passing. Deliberate bodily contact is not allowed. Goals thrown during play count two points, and goals thrown from free throws after infringements one point. Height is an asset in the game, which demands stamina and agility, and which has been highly recommended as an ideal training activity by coaches of other sports, particularly Athletics (*q.v.*).

Girls also play Basketball, and, in Britain, there are national championships for clubs and schools, and international matches between England and Scotland.

Biathlon. *See* Winter Sports.

Billiards.

Billiards, which originated in France, is a game of angles, and of very great skill. It is played on a table measuring 12 feet by 6 feet 1¼ inches, having six pockets, one at each corner, and one in the middle of each side. The table is covered with green baize, the edges being of cloth-covered rubber, called "cushions." Across the table, 2 feet 5 inches from the bottom edge, is a line, called the "baulk" line, the space between the line and the bottom of the table being "baulk." On the baulk side of the line there is a semi-circle with a radius of 11½ inches from the centre of the line. Down the centre of the table are four

"spots," one 12¼ inches from the top, one mid-way between the top and the centre, one in the centre, and one in the middle of the baulk line. Two white balls, one with a spot for identification purposes, and one red one, are used, the balls being played with "cues" that taper down to a striking tip. The remaining equipment includes a long, cue-like stick with a metal cross fixed diagonally on the end, called a "rest" or "jigger," and a special long cue, these being used when the player cannot reach his ball in the ordinary way. Most games are "singles," though "doubles" can be played, the object of the game being to score points according to fixed rules, an agreed number of points making the game.

To decide who is to start, players "string" by playing their balls simultaneously from baulk up to the top cushion, the ball which returns nearer to the bottom cushion winning. At the start, the red ball is "spotted" on the top spot, and players start from the baulk circle. Scoring is three for pocketing, or "potting," the red or going in off the red; two for potting the white, which is, of course, the opponent's ball, or going in off the white; and two for a cannon, which is hitting both the other balls. A player whose shot hits no other balls at all gives one point to his opponent, unless his ball goes into a pocket, when he forfeits three. A player's turn, called a "break," continues as long as he is actually scoring. When the red is potted, it is immediately respotted.

Snooker. Also played on a billiard table, and perhaps even more popular, is Snooker, which uses 22 balls, positioned as follows: 15 reds in the form of a triangle with its apex on the second spot from the top, and its base at the top end; a black on the top spot; a pink touching the apex ball of the triangle; a blue on the centre spot; a brown in the middle of the baulk line, with a green beside it on the left end of the baulk circle, and a yellow on the right end; and a white, which is the cue-ball to be played. The points values of the balls are from one for red, through yellow, green, brown, blue, and pink, to seven for black. A player's turn continues as long as he scores, his first shot being at a red, when, if he pots one, he plays at one of the other colours, play being at reds and colours alternately as lon as balls are being potted, and as long as there are reds on the table, after which the remaining colours are played in ascending order of value.

A variation of Snooker is Snooker Plus. This uses two additional balls, an orange, placed between the pink and the blue and valued at eight points, and a purple, placed between the blue and the brown and valued at ten points.

Pool, Russian Pool, and Pyramids. Other games played on a billiard table include Pool, Russian Pool, and Pyramids. In Pool each player has a ball of a different colour, the order of play being white, red, yellow, green, brown, blue, pink, black. Each player plays at the ball of his predecessor, and tries to pot it, the game starting with white spotting his ball on the top spot, so that red is actually the first to play. A player whose ball is potted loses a life, players losing three lives dropping out of the game. A turn continues as long as a player is potting balls, and if he clears all the balls on the table he then spots his own ball for the next player.

Russian Pool uses the yellow, green, blue, and black balls, with the white as cue-ball, the black being placed on the top spot, the blue on the centre spot, the green on the left side of the baulk circle, and the yellow on the right side. A player's first shot must hit the black, after which he can play at will. Scoring is by potting balls, by going in off balls, and by cannons, but the black can be used only for the top pockets, the blue for the middle pockets, and the green and the yellow for the bottom pockets. Cannons count two, potting or going in off counting nine for the black, seven for the blue, five for the green, and three for the yellow. A player's turn continues as long as he is scoring, but consecutive cannons on the same balls are limited to 25, and the same ball must not be potted from the same spot more than three times in succession. A complete miss forfeits three points. A variation of Russian Pool the pink ball, which is spotted on the second from the top, counts six, and can be used any pocket.

Pyramids uses the 15 reds, starting in triangle, and a white cue-ball, the object bei pot the reds. A turn continues while a pla scoring, 8 balls potted ending the game.

Bird-watching. *See* Natural History and Studies.

Boat Races.

Race rowing is a strenuous sport that mak pretence of attracting as many active partici as some other sports and games; yet its history includes races with unusual stories them; races that are amongst the greatest a international sporting events; and one race provides what is probably the most enthusiast supported free sporting spectacle in the worl

That, of course, is the Oxford and Camb University boat race, rowed on the Thames Putney to Mortlake. First rowed in 183 has offered its excited public, which inc thousands of people with no connection o kind with either university, everything, incl runaway victories, dead heats, and even si boats. To all intents and purposes, this regular annual event, and has been so since but, in actual fact, every race is the result separate special challenge from the losers previous race to the winners of it. The rac an interesting parallel in the United States, Yale University, whose colours are dark annually meet Harvard University, which Cambridge, on a river called the Thames.

The Oxford and Cambridge race is the known annual race on the Putney–Mor stretch of the Thames, but it is by no mean only one. There are other races that a entries sometimes numbered in hundreds: e that are far too big to race abreast on the Th and so race in single file, with crews foll each other at fixed intervals in what are k as the Head of the River races. The bi of these is for crews of eight, but there are Head of the River races for women's crews, cover only part of this famous stretch of w and for single scullers. Single scullers also this course in a straightforward race in the field Sculls event, which ranks as the Eu Amateur Championship, and which was first one year after the first Oxford and Camb race, in 1830.

Head of the River races, but with a differ are also held between the colleges of Oxford Cambridge, where the Isis and the Cam, re tively, are much too narrow to permit stra forward racing. These are the Bump Rac which each crew endeavours to catch and the crew ahead of it, except for the leading which can concentrate on staying in When a bump is achieved, the two crews pul the bank, and change places for the next racing. The racing goes on for four days, a is, of course, the ambition of each crew, from the leaders, to register a bump on each

Back on the Thames, but farther down wards the port and docks of London, is the of a race that makes the Oxford and Camb race and the Wingfield Sculls look like r innovations. This is the annual race London Bridge to Chelsea for the Doggett's and Badge, a single sculling event open on young watermen who are within twelve mont completing their apprenticeship. It was fou in 1715 in honour of the House of Han and to commemorate the anniversary "King George I's happy accession to the t of Great Britain," by Thomas Doggett, a Du born actor connected with the Drury Lane Haymarket theatres, who regularly travelle the Thames in preference to using the roads who left a sum of money to perpetuate the which is now controlled by the Fishmon Company.

This race is more truly an annual one than almost any other event; for, while most so-called nual races have been subjected to long interptions because of the two World Wars, those alified for the Doggett races during those years re subsequently traced, and the races duly cided after the wars. The event is a colourful e, always followed by a barge carrying a batch past winners wearing the Coat and Badge, and o the cap, breeches, silk stockings, and buckled oes that go with them. The scarlet, pleated, ilted Coat, with its silver buttons and the large ver arm Badge bearing the White Horse of anover and the word "Liberty", are presented the Fishmongers' Hall, where the winner is eeted with a salute of trumpets and the tune. See the Conquering Hero Comes."

For a rowing event of a very different kind, ting back "only" to 1839, one must go up the ames, far beyond the end of the Tideway, to enley, for the annual Royal Regatta. This nsists of events open to the world and others ssed to English colleges and schools for eights, urs, pairs, double sculls, and single sculls, the ost famous of its races being the Grand Challenge p for eights and the Diamond Sculls.

A journey far from the Thames will bring to light e story of a rowing trophy that first appeared tteen years before Oxford first met Cambridge. he Carrow Cup was awarded for a four-oared race the River Yare, in Norfolk, from Carrow Bridge Whitlingham and back in 1813. Sometime ring the 1840s that cup disappeared: to reppear in 1890—in Australia. In 1947 it came o the possession of the Victoria Rowing ssociation, which made it the trophy for a pairred race, but sent it to England for exhibition the 1948 Olympic rowing museum. There it as recognised as a Norfolk trophy, and, though returned to Victoria, it came home again in 1950, hen the Melbourne club gave it to the Norwich owing Committee, which now annually awards to "the Norwich club whose general performnce, judged by a points system in Regattas, shall best."

wls.

Bowls, one of the oldest of all games, was once garded as "an old man's game," but it actually s many devotees of all ages and both sexes, and played indoors as well as outdoors. It certainly es back to the thirteenth century, when its pularity made it one of the games legislated ainst as likely to draw people away from chery. Henry VIII played; and the famous me on Plymouth Hoe, in which Sir John awkins stayed to beat Sir Francis Drake even er the Armada had been sighted, if not finitely authenticated, is accepted as fact by veral historians. It is interesting to note that, this game was played, it would have been alost identical with a game of to-day, for it was that century that the "bias" that is a leading ature of the bowls or "woods" was introduced. century later, however, Bowls, which was rely played on greens attached to taverns, quired a reputation as being merely an adjunct pot-house revelry, but it was revived on a gher level in Scotland, and never again came so ar to oblivion.

There are actually two games of Bowls, the nk or Level Green game and the Crown Green me, and it is the rinks rather than the objectives at differ. The Level Green game is the more dely played, and it takes place on a perfectly t piece of well-cared-for turf. The Crown een game, which is popular in the North and dlands, is played on a green of which the centre 6 inches or more higher than the corners. The games differ—for instance, in the putting into play of the object ball—but only slightly, so it will be appreciated that the Crown Green game demands a good deal of experience and skill. It is mainly a singles game, whereas the Level Green game is played between sides consisting of one, two, three, or four players.

Bowls looks a simple game, the object being simply to place the bowls as near as possible to the object ball, or "jack." The bowls, however, are "biased," and the game is actually one of considerable skill. When bias was introduced, it took the form of weighting with lead, but it is now achieved by turning one side of the bowl less round than the other. Level Green bowls weigh up to 3½ lb., but Crown Green bowls are smaller and less biased. On the Crown Green, however, the jack, which is played into position by the first player, is also biased.

Players normally use two bowls in a game, or four in singles, and the side with the best record of bowls near the jack wins the "end," and the best record of shots in an agreed number of ends the game.

A Bowls green is such a perfect piece of grass that it might be thought that the expression "rub of the green," used to describe an unavoidable piece of bad luck, comes from this game. In actual fact, though, it would probably be more correct to attribute this phrase to Golf (*q.v.*).

Boxing.

Boxing, sometimes called "The Noble Art of Self Defence," though actually aggression is its keynote and defence an incidental, is a modern continuation of the old sport of prize-fighting, which, though always illegal, was popular from the time of the Regency until it was succeeded by the present-day glove-fighting at the end of the nineteenth century.

In prize-fighting bare fists were used, and wrestling holds were allowed. Rounds ended when a fighter went down, and fights continued until, following a knockdown, a man failed to come up to the scratch line in 30 seconds.

In modern boxing, gloves are worn, and no wrestling is allowed. Rounds last for a fixed time, generally 3 minutes with 1 minute between rounds, and fights last only for a fixed number of rounds, never more than fifteen. A knockdown does not end a round, the man who is down having 10 seconds in which to rise. If he fails to do so, his opponent wins by a knock-out. If a man fails to come up at the beginning of a round or if the fight is stopped to save a man from further injury, the victory is by a technical knock-out. If, however, both men are still on their feet at the end of the stipulated number of rounds, a decision is given on points. Boxing is therefore technically a contest of skill for points, and, as such, far removed from prize-fights to a finish.

Fights are controlled by a referee, and, in British professional boxing, he is solely responsible for any points decision. In amateur boxing the decision is given by several judges, who sit apart from each other. The difference between a good professional and a good amateur is probably more marked in boxing than in any other sport

Boxing contests are arranged in classes according to weight, the divisions being: fly-weight, up to 8 stone; bantam-weight, up to 8 stone 6 lb.; feather-weight, up to 9 stone; light-weight, up to 9 stone 9 lb.; welter-weight, up to 10 stone 7 lb.; middle-weight, up to 11 stone 6 lb.; light-heavy or cruiser-weight, up to 12 stone 7 lb.; and heavy-weight, any weight. In amateur boxing some of these weights are slightly different, and there are two additional classes, light-welterweight, up to 10 stone, and light-middle-weight, up to 11 stone.

Prize-fighting was governed successively by "Broughton's Code," the "New Rules of the Ring," and the "London Rules." Then, in 1867, the eighth Marquess of Queensberry and Mr. J. G. Chambers drew up the rules that have been the basis of boxing ever since. British professional boxing has been controlled since 1929 by the British Boxing Board of Control. The Amateur

Boxing Association has governed amateur boxing since 1884, when it took over from the Amateur Athletic Club, which had looked after both boxing and athletics.

Prize-fighting is finished, but it has left a legacy, not only in modern boxing, but through an expression that has become part of the language, for the phrase "come up to scratch" originally referred to a prize-fighter stepping up for a new round.

Bridge.

Auction. Auction Bridge is a card game in which two partnerships of two oppose each other, each player facing his partner. A complete pack is used, the suits having special values, ranging from 6 points per trick for Clubs, through Diamonds, Hearts, and Spades, to 10 points per trick for No-trumps. When bidding, it is the points value of the bid, and not the number of tricks bid, that decides seniority, though the highest number of tricks prevails when the points values are equal. If a bid, or contract, is doubled or redoubled, the trick score is doubled or redoubled.

A player may pass, but, should he bid under the previous bid, he can be penalised, the player on his left having the option of closing the bidding at the previous bid or demanding that the offender make a proper bid. In this case, his partner is barred from bidding again unless the opponents do so. Should a player bid out of turn, the player on his left can demand a new deal.

Points are counted in two ways, below the line and above it. Points below count towards game (30 points), and are awarded for all tricks over six made by the contracting side. Points above the line are gained in various ways, and count in the final score, but not towards game. The first side to win two games wins the rubber, and 250 extra points above the line. The holding of honours also wins points above the line, as follows: three honours, twice the suit value; four, four times the suit value; five, five times the suit value; four in one hand, eight times the suit value, four in one hand and one in partner's, nine times the suit value; five in one hand, ten times the suit value. At No-trumps the honours count for Aces is 30 points for three, 40 for four, and 100 for four in one hand. The points for defeating a contract are 50 for each trick by which the contract fails. Extra points for making a doubled or redoubled contract are 50 for the contract plus 50 for each trick over when doubled, and 100 for the contract plus 100 for each trick over when redoubled. 50 points are awarded for a little slam, which is 12 tricks, and 100 for a grand slam, all 13 tricks.

The player who first named the contract suit is the declarer, and his partner is dummy. After the lead, which comes from the player on declarer's left, dummy lays his hand face upwards on the table, and it is played by declarer, dummy having only limited rights of intervention. If his partner fails to follow suit, he can ask him if he has no cards in the appropriate suit; he can draw attention if too few or too many cards are played in a trick, or if the wrong side gathers up the trick; he can discuss questions of fact, and correct any claims made by the opponents to which they are not entitled. He cannot draw attention to any revoke; he cannot claim any penalty; and he cannot warn his partner against leading from the wrong hand.

Revoking is failing to follow suit when this is possible, the revoke becoming established when the player or his partner plays to the next trick. Up to then, the offender may correct it. The penalty is 2 tricks for the first revoke, and one for subsequent revokes, the penalty tricks to be taken only from the trick in which the revoke occurred or later ones.

A lead from the wrong hand may not be withdrawn unless the opponents request this. If they do, the card is replaced, and play continues. If declarer's opponents lead from the wrong hand, declarer may either demand a lead in a particular suit from the right hand or reserve the right to have the exposed card played whenever he ch to call for it. In this case, though, the offe may play the card before it is called, if he ha opportunity.

Contract. At Contract Bridge only the t contracted for are scored below the line, tricks being recorded above it. The score tricks is 30 in a major suit (Spades or Hearts) 20 in a minor suit (Diamonds or Clubs). In trumps the first trick counts 40 and subseq tricks 30. In bidding, the highest numbe tricks prevails, regardless of suit values.

A game is 100 points, two games won stituting a rubber, which carries a bonu 700 points, if the opponents have not won a g In an unfinished rubber, a game gains 300 p and a part score 50, provided the opponents ha part score at all. A side winning a game bec vulnerable, and this affects subsequent scorin

Penalties for failing to make a contract 50 points per undertrick if the declarer is vulnerable and 100 points per undertrick if I If an opponent has doubled, the penalties are for the first undertrick and 200 for subseq ones if not vulnerable, and 200 for the first u trick and 300 for subsequent ones if vulner If the declarer has redoubled, these penalties doubled. In successful contracts doubled, tricks score 100 if declarer is not vulnerable 200 if he is. A successful doubled or redou contract wins a bonus of 50 points. Bonuse awarded for making slams, if they have been If declarer is not vulnerable, the bonuses are for a small slam (12 tricks) and 1000 for a g slam (13 tricks). If vulnerable, the bonuse 750 and 1500. Honours points are 100 for honours in the contract suit in one hand; 15 five honours in one hand; and, in No-tru 150 for four Aces in one hand.

A player making an insufficient bid ma required either to pass or to make a suffi bid. If he passes or makes a sufficient bid different suit, his partner is barred from fu bidding. A call out of turn is void, but, if t a pass, the offender must pass in his turn, a it was not a pass, his partner is barred further bidding. A player has no redress misunderstands a bid, though he can ask for or a sequence of bids to be repeated. W three successive players have passed, the con is fixed, declarer being the first player on contracting side to nominate the suit, and du being his partner.

Dummy is entitled to ask for or give info tion on the laws, to point out revokes and t prevent those about to occur, and to remin partner from which hand he should lead, however, he looks at any hand other than his he forfeits these rights.

If declarer leads from the wrong hand opponents can demand a lead from the co hand; and, if it is possible, this must be i same suit. If a defender leads when it is declarer's turn, the card becomes a penalty If a defender leads when it is his partner's declarer may either bar a lead in that su make the exposed card a penalty card. A pe card must be played at the first legal opportu

Contract Bridge is a game of systems. T are systems for assessing the value of a hand there are more important and more inv systems governing bidding, the object of being the interchange of information bet partners.

Bumping Races. *See* Boat Races.

Camping.

Camping expresses the townsman's desire t away from cities and fend for himself in c But some organisation is necessary to pr camping facilities and to maintain high stand The Camping Club of Great Britain has a mem ship of over 50,000. Its work is twofold

elects sites suitable for mobile campers and aravanners; and establishes and maintains well-quipped permanent camping grounds. A *Sites List* published annually contains details of 2,000 amp sites. Members agree to abide by the lub's Code of Campers, which stresses the need of he camper to pay full regard to the countryman's ray of life and to maintain by country courtesy he goodwill of those among whom he camps. The Club's address is 35 Old Kent Road, London, .E.1.

anadian Football.

Canadian Football resembles American (*q.v.*), ut is twelve-aside, uses only three downs, and imits blocking.

anoeing.

Canoeing is both a recreation and an organised ompetitive sport.

As a recreation, it can take the form either of imply taking a canoe out and "paddling about" or a short period or, by combining it with Camp-ng (*q.v.*), of a lengthy and interesting river trip, he canoe-camper proceeding, of course, at his wn pace, and giving as much time as he wishes o sightseeing.

As a sport, Canoeing has Olympic Games status. n Britain it has its headquarters on the Thames t Teddington in Middlesex, the governing body eing the British Canoe Union. There are races or singles and pairs, including events for women. here is also one long annual race for pairs that eally combines Canoeing with Camping. The ourse is from Devizes in Wiltshire to London, nd the competitors have to negotiate a long eries of locks.

There are two types of canoe: Canadian canoes, ke those used for many years by Red Indians, nd kayaks, the very light Eskimo-type canoes, which an expert, but not a beginner, can turn a omplete circle into the water and out again with-ut losing his seat in his craft. Both types are atered for in the Olympic Games, but most of the anoeing in Britain is in kayaks.

ard Games. *See* Bridge; Patience; Solo Whist; Whist.

hess.

Chess, greatest of all board games and a game f pure skill, has a known history of some 1500 ears. Eastern players, who originated it, eached a high standard, but the game's greatest dvances were made in Italy in the fifteenth and xteenth centuries. In the early days the value f the pieces and their moves underwent periodical hanges, but the game we know to-day dates from he sixteenth century.

The board has 64 squares in eight rows of eight, nd each player has 16 pieces, one set being white nd the other black or red, but always referred to s black. A toss decides possession of white, hich always starts. The object is the capture f the opponent's King, no matter how many ieces are lost in doing so, nor how many opposing ieces remain untaken. If the King could be aptured on the next move, it is in "check." must be released from check (by moving, by overing, or by capture of the checking piece), herwise it is "checkmate" and the game is over. the King is not in check, but cannot move except to check, and the player has no other pieces he n move, it is "stalemate," and a draw. Games ay also be drawn if neither player has sufficient ieces to force a win.

In addition to the King, each player has a ueen, two Bishops, two Rooks—sometimes rongly called Castles—two Knights, and eight awns, and all these move in accordance with xid rules. The following diagram shows the ieces at the start of a game:

(The initial position as seen by White)

Each line of squares across the board is a "rank," and each line up and down the board is a "file."

The permitted moves are as follows:—

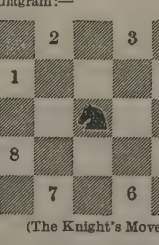
The King can move one square at a time in any direction.

The Queen can move in accordance with the powers described below for both Bishops and Rooks.

The Bishops move diagonally as many squares as desired.

The Rooks move straight along the ranks or files as far as desired.

The Knights move as shown in the following diagram:—



(The Knight's Move)

Stationed away from the side of the board, and on a black square, the Knight illustrated can move to any of the numbered white squares. The move is one square along rank or file in the desired direction, and one square diagonally. The Pawns move straight forward, one square at a time, but may move two squares when moved for the first time. They capture by moving one square diagonally forwards. A Pawn reaching the eighth rank may be replaced by any other piece

Once during a game, a player may "Castle," by moving the King two squares towards the Rook, which is placed on the last square passed over by the King. This move cannot be made if either

the King or any of the squares he would pass over are in check. Neither King nor Rook must have moved previously.

Games of Chess can be recorded, so players can play over great "Masters" games, and record their own games.

Draughts. Draughts—called Checkers in America—is also played on a chess board. Possibly older even than Chess, it is much simpler, but not devoid of skill.

Each player has twelve pieces or "men," all alike. Squares of one colour only are used, the men starting on the first three rows on the board. The move is one square diagonally forward, but a man reaching the eighth row becomes a "King," and may then move forward or backward. The object is the capture of all the opposing men by jumping over them. If the arrangement of the men permits it, more than one man may be captured in a single move. A man which can effect a capture but does not do so is removed from the board, or "huffed."

Cricket.

Cricket, traditionally England's national game, has a longer history than most team games. There have been attempts to trace its origin in various games played by ancient races; and, even if some of these derivations are a little far-fetched, it certainly developed from very old country games, and has been played in a form not so very dissimilar from that of to-day for over 250 years. The men of Hampshire, particularly the village of Hambledon, Surrey and Kent were the real pioneers of the cricket of to-day.

Cricket is played by two teams of eleven players, which bat and field in turn. In the centre of the ground are two "wickets," 22 yards apart, and each consisting of three "stumps," joined at the top by two "bails." The bats used have a flat striking surface, and the ball is a hard red one weighing 5 ounces.

There is a batsman at each wicket, and their object is the scoring of runs by hitting the ball away, and running before it can be returned, each time the two batsmen cover the length of the pitch counting as one run. Should the ball be hit beyond the boundary line round the ground, it counts four or, if it crosses the line without touching the ground six.

The ball is "bowled" from one wicket to the batsman at the other, six balls, or, in some cases, eight, which comprise an "over," being bowled from each end in turn. The object of the fielding side is to get the batsmen "out," ten dismissals completing the "innings," as the eleventh man is left without a partner.

A batsman can be dismissed in several ways. If he misses the ball and it hits the wicket, or if he plays it on to the wicket, he is out "bowled." If he leaves his ground, indicated by a line in front of the wicket, misses the ball, and has the wicket "broken" by the wicket-keeper he is out "stumped." If he hits the wicket with his bat he is out "hit wicket." If his hit is caught he is out "caught." If, when running, he fails to reach his ground before the wicket is "broken" he is out "run out." If a ball, when bowled, would have hit his wicket, but hits his leg instead, then, subject to certain provisions regarding where the ball actually pitched, he is out "leg-before-wicket." A batsman may also be given out if he handles the ball or obstructs the fielding side, but these are rare occurrences.

In addition to runs hit by the batsmen, there are certain "extras." If the ball passes the bat, misses the wicket, and goes far enough for the batsmen to run, it is a "bye." If, however, it goes off the batsman's leg it is a "leg-bye," but leg-byes cannot be run unless the batsman was definitely attempting a stroke. If it is bowled so wide that the batsman cannot reach it, it is a "wide." If the bowler comes in front of his wicket before releasing the ball, or if he throws it, it is a "no-ball," in which case the umpire ca it as quickly as he can, for the batsman can such a ball, but he cannot be out to it, unless is run out. If he does not score, one extra addsd.

Of the fielding side, one, of course, is the bowl and another, placed behind the batsman's wick is the wicket-keeper. The others will be plac as the bowler and his captain decide, for there far more recognised positions than can be occupi at one time. To gain some idea of these positio imagine a right-handed batsman at the wick his left side towards the bowler. The side of t wicket in front of him, nearer to his bat than to body, is the "off" side; the side behind hi nearer to his body than to his bat, the "leg" si On the off, behind the wicket and close to it, the "slips," and, behind them, "third man Farther round, but still behind the bat a close to it, is "gully." Level with the bat "point" or, if he is some way from the bat, "de point." In front of the bat, but in front also of t bowler's wicket, is "cover" and "extra cove Roughly level with the bowler's wicket is "m off," with, behind him, "long off." Simila on the leg side, where "long on" is the equiva of "long off," "mid-on" or "mid-off," "m wicket" and "deep mid-wicket" or "cove and "extra cover," "square leg" and "de square leg" or "point" and "deep point," "sh leg" of "gully," "long leg" of "third man," a "leg slip" of "slip."

First-class cricket matches last for three s hour days or longer, but there are also two-d one-day and half-day matches. Matches of t days or more are two-innings games; of one d or half a day, one innings. If the side batti first, which is decided by a toss that gives t winner the choice of batting or fielding fir dismisses the opposing side for a smaller sco the victory is by the number of runs by which t smaller score was exceeded. If the side batti second pass the other total, the game ends, and t victory is by the number of wickets the second s still have standing. In a two-innings mat should the side batting first gain a first-innin lead of a certain size, normally 150 runs in a thr day match, it can require the other side to foll straight on with its second innings, the leadi team keeping its second innings in reserve, be played if needed. If a batting side h sufficient runs, and is anxious to see the other a batting while there is still plenty of time dismiss it, it can declare its innings closed. this case, should the second team score enou runs to win, it does, in fact, win, even though may have lost more wickets than had the decl ing side.

Cricket is not a fast-moving game, and years views have been expressed to the effect th it must be "brightened up" if it is not to die o Periodically, small changes in the rules are mad but, for the most part, the game just goes stead on, easily retaining a large following that satisfied with it as it is, and still able, when l international matches take place, to command place, not only on the sports pages, but on t front pages of the Press.

The game is unusual in that it has no rea official governing body. It is ruled by the M.C. which stands simply for Marylebone Cricket Cl from its headquarters at Lord's ground in Londo and the M.C.C.'s pronouncements are accept almost without question.

Outside England, the development of cricl has been peculiar. Even as near at hand Scotland and Ireland, the game has never arou much enthusiasm; and in Continental Euro where many British games have won gr acclaim, cricket has gained a real foothold only the Netherlands and Denmark. In the Unit States and Canada it is played, but only to a sm extent. However, in Australia, South Afri New Zealand, the West Indies, India, and Pa stan, it is extremely popular; and the natio teams of these countries, together with Engla provide the top-class international sides of t game. They meet regularly in "Test Matche a "rubber" normally being decided in a series five Tests. *See* U34.

Cricket is rich in technical terms and expressions, which are seen and heard frequently through newspapers, television, and radio when a Test series is in progress. Many of these are almost self-explanatory, but a few never fail to puzzle less-experienced readers, viewers, and listeners. Prominent amongst these are three types of ball used by bowlers, the "yorker," the "googly," and the "chinaman."

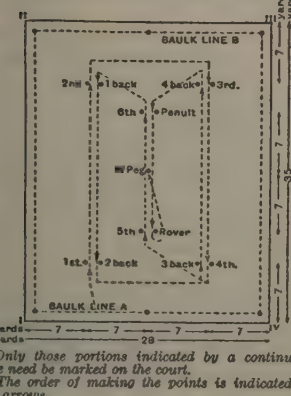
A yorker is a fast ball that pitches just in the batsman's block-hole, and often passes under his defensive stroke. The term is believed to have originated in Yorkshire, but the only known explanation of it is that attributed to a Yorkshire cricketer, who, asked why a yorker was so called, replied simply, "Well, what else would you call it?" There is an answer to that, for the yorker was originally known as a "tice." A googly is an off-break or a leg-break which is disguised, because the bowler has delivered the one with the action of the other. A chinaman is an off-break bowled by a left-handed bowler to a right-handed batsman. These words also lack an authentic derivation.

Cricket has provided one expression that is now heard in many connections. That is "hat-trick," which dates back to the days when cricketers wore top-hats, and any player who took three wickets with three successive balls was presented with a white top-hat. Now, he is usually given the ball.

Croquet.

Croquet originated in France, and has been played in Britain for about a century. The governing body, the All-England Croquet Club, was founded in 1868, with headquarters at Wimbledon. Soon afterwards, this also became the head-

STANDARD SETTING.



Only those portions indicated by a continuous ne need be marked on the court.
The order of making the points is indicated by e arrows.

quarters of Lawn Tennis (*q.v.*), and it is probable that the rapid growth of that game was a factor that restricted the development of Croquet. Croquet, however, still retains a following, and, in addition to Championships and tournaments, is widely played on private lawns.

The equipment consists of four balls, coloured blue, black, yellow, and red; four mallets, usually marked with the same colours; six hoops; and a peg. The playing area is 35 yards by 28 yards, but this can be reduced, provided that the proportion remains 5 to 4. The hoops, which stand 1 foot out of the ground, and the peg are placed as shown in the diagram. Generally two players, taking the blue and black balls, oppose two using the yellow and red, but singles can be played, each player using two balls, blue being paired with black, and yellow with red. Each player completes the circuit of hoops twice, finishing by hitting the peg.

Croquet is a game of skill, and players can earn extra turns in various ways, such as hitting another ball with their own or passing through hoops. While making their own circuits, players also concentrate on leaving their opponents at a disadvantage. Handicap matches are possible through the giving of extra turns, or "bisques." A "half-bisque" is an extra turn in which no hoop may be scored.

Croquet can, perhaps, claim some credit for a phrase used in everyday life. "Pegging out" has the rather sinister meaning of "dying" or "finishing," but it is actually the term used for finishing a Croquet round by hitting the peg.

Cross-country. *See* Athletics.

Cruising on Inland Waterways.

For those who want a touring holiday in Britain away from crowded roads, but who do not want to walk or ride, cruising on inland waterways offers a pleasant and interesting alternative. Facilities are available on a number of canals, rivers, and, of course, the Norfolk Broads; and motor-cruisers can be hired, complete with sleeping accommodation, bed linen, and cooking utensils. At some places, for example, the upper reaches of the Thames, those who prefer to do so can hire cruisers without sleeping accommodation, and spend the nights at riverside inns. The Inland Waterways Association exists to keep the waterways open and, where possible, to re-open others. Particulars of available facilities can be obtained from the Association at 114 Regent's Park Road, London, N.W.1.

Cycling.

As a pleasant recreation, cycling offers a wide range of possibilities. Outings can be for a day or part of a day, or they can be tours of any length the rider wishes, with the overnight halts spent in hotels or hostels or Camping (*q.v.*), which can easily be combined with cycling.

As a competitive sport, cycling offers a remarkable variety, for no other form of racing provides events of so many different types. On the Continent, cycle racing is by far the most popular sport, and the leading riders are national heroes. The sport, which caters for both amateurs and professionals, also has a large following in Britain, where it would soon progress still farther if there were more tracks suitable for big events available.

Cycle races are held on banked tracks rather like motor-racing tracks, on flat grass tracks, on cinder tracks, on indoor banked board tracks, on roads, and even across country. There are races at all distances, from short sprints to road tours divided into daily stages lasting for several weeks. There are massed-start races, in which all the competitors start together; races in which competitors are drawn in twos or threes through several rounds up to a final; and time trials, in which each rider starts alone. Track races may be straightforward races or time trials; or motor-paced, with the riders behind motor-cycles; or tandem-paced; or pursuit races, with riders or teams of riders starting on opposite sides of or spaced round the track; or point-to-point, with points awarded to the leaders at the end of each lap; or courses des primes, with a prize for the leader at the end of each lap; or Madison races, for teams of two, and occasionally three, riding one at a time, and relieving each other at will. There are also races for tandems and tricycles; and the sport includes races on both track and road for women as well as men.

In the cross-country side of cycle racing, called Cyclo-Cross, riders cover a cross-country course of perhaps 10 miles, riding when they can and carrying their machines where riding is impossible. Still another form of cycle racing is roller racing. In this, the cycles are fixed on rollers, and do not move at all, the distance the riders pedal being registered on large dials. There is also cycle

speedway, a sport devised by youths, and practised only by youths. Events take the form of team matches, generally on rough cinder tracks constructed on waste ground by the youths themselves, with pairs of riders opposing rival pairs in a series of races, and points awarded to the leaders in each race. Corners have to be "skidded" round, as they sometimes are in ordinary grass-track cycle racing. Very different, but still competitive in a way, is a form of event that provides a link between the sporting side of cycling and the more purely recreational side, the reliability trial or attempt to achieve a fixed standard.

Cycling also has its team game in Bicycle Polo, a hard game requiring a high level of cycling skill and considerable nerve.

There is also an organisation that caters especially for the distance tourist in the Cyclists Touring Club, which keeps a check on premises offering accommodation to cycle tourists, and provides a sign for use on approved accommodation. It is interesting to note that the Automobile Association, which offers similar services to motorists, but which is not as long-established as the C.T.C., originally based its methods on those of the C.T.C. The C.T.C. address, for those who might be interested in joining, is 3 Craven Hill, London, W.2.

Darts.

Originally just a casual amusement confined almost entirely to public-houses, the game of Darts is now one of Britain's most popular pastimes. Public-houses still provide facilities for it, but to-day clubs, canteens, factories, offices, and private houses also have their boards, and there are numerous team and individual competitions, including a National Championship. The prizes rival those of any other game for value, matches are widely reported, and the attendance for the bigger contests is limited only by the size of the hall. This enthusiasm is not misplaced, for the game is a test of skill, and luck plays little part in it.

The circular board has a diameter of 18 inches, and is divided into segments numbered from 1 to 20, but not consecutively. In addition, there are two rings, each 1 inch wide, that go right round the board and through each segment. These are the "double" ring, at the extremity of the board, and the "treble" ring, near the centre of the board, darts in these rings counting double or treble the value of the segment. In the centre of the board there are two small rings, the "bull" or "dosser," counting 50, and the "outer," counting 25. The bull is 5 feet 8 inches from the ground, and the wooden or metal feathered darts are thrown from a line, called the "hockey," 9 feet away.

Matches may be singles, doubles, or between teams of four or eight players. Games are for a certain number of points, usually 101, 201, 301, 501, 801 or 1001, the lower totals being used for individual, and the higher for team contests, and matches are generally the best two out of three games or "legs." Conditions for matches vary, but normally stipulate either "straight start and finish on a double" or start and finish on a double." In the first case players score from the start, but in the second they do not score until one double has been registered. In both cases they must finish on a double, and they must finish with the exact number they require. Scores are counted downwards, players being told how many they need, rather than how many they have scored.

In addition to the straightforward game, there are many Darts variations. In one, "Round the Clock," a player has to throw one dart into each segment from 1 to either 20 or the bull, his turn continuing until he throws three darts unsuccessfully. In "Shanghai," players start with a complete throw of three darts at number 1, and continue with a throw at every number up to 9, but players who fail to score at number 5 drop out. In "Cricket," one player "bats," throwing normally, and counting everything over 40, while the other "bowls," throwing only at the bull, and counting one wicket for every "outer" and two for every "bull," five wickets ending his opponent's "innings." In a Darts version of Shove-Ha'penny players have to get three darts in each segment from 1 to 9, and three in the centre. In "Fives," players score only if the total is divisible by five.

Diving. *See* Swimming.

Dominoes.

Dominoes are similar in many ways to cards, that many games can be played with them with varying degrees of skill. Players play (or *put* or *down*) in turn from hands. The game was introduced in Europe by way of Italy in the 18th century, though the actual games as they are played today, and also the scoring methods, are of French origin.

The domino itself (called a *card* or *stone*) is an oblong with its face divided by a centre line and marked in each half by indented dots. A set normally consists of 28 pieces, respectively marked 6–6 (double six), 6–5, 6–4, 6–3, 6–2, 6–1, 6–0, 5–5, 5–4, 5–3, 5–2, 5–1, 5–0, 4–4, 4–3, 4–2, 4–1, 4–0, 3–3, 3–2, 3–1, 3–0, 2–2, 2–1, 2–0, 1–1, 1–0, and 0–0 (double blank). (There are special sets for games consisting of 55 pieces, running up to 9–9, and of 91 pieces, running as high as 12–12).

In the common form of the game, using 28 pieces, the dominoes are laid face downwards on the table, each player taking seven, the rest being left as a reserve. A player stands his hand so that the faces of his pieces are visible to him but not to his opponents. The idea of the game is to match the number on one domino-half to that on the free half of a piece already played on the table. Pieces are laid end to end but double pieces are laid transversely and allow the player an extra turn. The winner is the one who plays all his pieces.

Variations include playing a piece that is not the same as the one to which it is fitted, but that with it, adds up to seven, or one that will make two ends of the line add up five or a multiple of five, or three or a multiple of three. Another variation makes the double-blank and any piece on which the two halves add up to seven *matadors*. These are the equivalent of the card player's trump cards, and may be played at any time.

In some games, a player who cannot play simply misses the turn, while, in others, he may draw from the reserve, having, of course, to retain the domino in his hand if he still cannot play.

Games are for two, three, four or more players and, in some of those for four players, two play together against the other two, each player trying to block his opponents, but to assist his partner.

As with cards, solitary players can play Patience, and this is a good way for a beginner to learn how to play a hand. The player picks the dominoes from a shuffled set, starts with any piece he chooses, and then continues to play in the normal way. When he cannot play, he draws enough pieces from the reserve to make his hand up to five and carries on, continuing until either he can play out or cannot play at all from the pieces left.

In the more skilful games, as in the more skilful games of cards, a good memory is an asset, as it is essential to remember which player played which piece. Despite the claims of many more modern pastimes, dominoes is gaining in popularity, particularly in such places as works' canteens; there are now almost certainly more players in Britain than there have been at any time since before the first World War.

Drama

Few countries can boast so eager an interest in amateur drama as Britain, and it is estimated that there are some 20,000 groups in the British Isles with half a million membership. The central influence in this enormous movement is the British Drama League, to which some 3,500 groups belong besides nearly 2,000 private individu

The league's influence on drama is exercised in two ways. Its members have the use of the library, which possesses the largest collection of plays and books on the threatre in Great Britain and of its information services, which give help and advice on every conceivable dramatic topic. They can, of course, hire sets of plays (one copy for each character up to twelve.) Then there are the League's training schemes. Courses in production, acting, and décor take place in London all the year round, and there are summer courses in the country. The address of B.D.L. is 9–10 Fitzroy Square, London, W.1.

It was not until the great International Theatre Exhibition at the Victoria and Albert Museum in 1922 that the English public became fully aware of the "new man" who had arrived in the theatre —the "producer" or "director," as the Americans call him. It is the producer who decides how the play is to be produced and sets his signature upon it, very much like the conductor of an orchestra. In this task he unifies the work of the author, actors, designers, and craftsmen of various kinds. The technical side of staging a play is a fascinating one involving problems of the framework (the stage, sight lines, auditorium); curtain settings, lighting, skycloths; the construction of scenery; designing the scenery and the making of scale plans and models; painting the scenery; lighting, and so on.

Television offers new opportunities for the playwriting aspirant, with its need for new methods. In the theatre the playwright and actor must make all things plain to distant members of an audience—whereas the television actor's slightest change of expression is clear to the person sitting within a couple of yards of him. A wink, a nod, a shrug on the television screen suffice for the implications which would be lost in the theatre. The gearing, so to speak, between text and meaning is different. A new field opens, therefore, for the writer for television drama.

Draughts. *See* **Chess.**

Eton Fives. *See* **Fives.**

Fencing.

Fencing can claim a longer history than most sports, for it is the modern equivalent of duelling. In mediæval tournaments mounted knights fought with lances, and, in addition to actual fights to the death, they also met with special, less lethal lances purely for sport. Later, duels were fought dismounted, and with different weapons. In Elizabethan days duellists used a sword, for attacking, in the right hand, and a dagger, for defence, in the left. Later still, the dagger was discarded, and duels were fought, as are fencing bouts to-day, with a sword only.

Duelling declined in Britain during the Regency period, when it became fashionable for gentlemen to learn to fight with their fists, but they continued to learn swordsmanship, and to fence with the practice weapon, the foil. Eventually, duelling became illegal almost throughout the world, but swordsmen of other countries similarly continued to fence with the foil. Even before Britain took to fist-fighting, most of the advances in fencing technique had been made in France and Italy, and the fencers of these and other Continental countries are still the best in the world, countries like Britain and the United States relying largely on fencers of Continental European descent.

Duelling was restricted to "gentlemen," and something of this restricted atmosphere pervaded the early days of fencing as a sport, clubs being few, expensive, and rather exclusive. Now, however, that has changed, and widespread class tuition in fencing has opened the sport to anyone.

Modern fencing includes contests with three weapons: the foil, which is the only one used by women; the épée, the real duelling sword; and the sabre, which cuts as well as thrusts. These weapons have "buttons" on the points, but fencers wear a special glove, a padded jacket, and a mask. Fencing requires grace of movement, lightness of foot, agility, strength of wrist and forearm, quick mental reactions, and good eyesight; and it will do much to develop these qualities, including the eyesight. As masks are worn, it is perfectly practicable to fence wearing glasses.

Figure Skating. *See* **Skating.**

Fives.

There are two games of Fives, Eton Fives and Rugby Fives. They are court games using walls, but an Eton Fives court has the addition of a buttress or "pepper" jutting out from one side wall. The striking implement is the gloved hand. Eton Fives is a doubles game, but both singles and doubles are played in Rugby Fives.

Folk Song and Dance.

Whether or not you play, sing, or dance yourself, you can enjoy the heritage of English folk music, song, and dance. To enable you to enjoy it to the full the story of Cecil Sharp House will be useful. Cecil Sharp went out to collect the folk songs of England in the fields and cottages, in almshouses, and by the roadside. He systematically combed some counties like Somerset. Cecil Sharp and Vaughan Williams joined the English Song Society, which had had Elgar and Parry among its first members. Sharp went on to note down folk dances and to publish details of the steps and figures. In course of time he founded the English Folk Dance Society to restore their traditional dances to the people of England. The two Societies amalgamated in 1932 and, today, Cecil Sharp House (2 Regents Park Road, London, N.W.1) is the home of the English Folk Dance and Song Society, with over 12,000 members.

Scottish Dancing and singing are the primary objectives of special holidays by the Holiday Fellowship at Scottish centres; and Old Time Dancing is enjoyed at an English Centre. Folk dancing is also the feature of special holidays by the Cooperative Holidays Association.

Football. *See* **American Football; Association Football; Australian Rules Football; Canadian Football; Gaelic Football; Public-School Football; Rugby Football.**

Gaelic Football.

Gaelic Football is seldom played by anyone who is not Irish, but it is frequently played outside Ireland, for Irishmen have taken it with them to Britain, the United States, Australia, and South Africa.

Played fifteen-aside, it is a blend of Association and Rugby Football (*q.v.*), the goals having the uprights, cross-bar, and net, exactly as in Association, but having the uprights extended above the cross-bar, as in Rugby. If the ball goes under the cross-bar it is a goal, and if it goes over it is a point, a goal equalling three points. The ball is round, and it may be kicked or caught, but not thrown forward, nor carried, though it may be dribbled by bouncing it. In its essentials, it is probably simpler than most other forms of football, but it is fast and involves frequent hard bodily contact. Substitutes are permitted in case of injury.

Gaelic Football joins with Hurling (*q.v.*) in coming under the old-established Gaelic Athletic Association.

Gliding.

The first serious efforts to develop Gliding which is flying in engineless aircraft or sailplanes making use of natural air currents, took place in Germany in 1919, and were successful enough to lead to experiments in France and England, where it arrived in 1922. At that time, however, it failed to gain much support, and the real history of gliding in Britain dates from a second attempt to encourage it in 1929. Little more than ten years later, gliding had advanced sufficiently to be a real factor in the second World War.

Skilful use of up-currents enables the glider pilot to stay up, and if the air is rising faster than the glider is sinking, the glider will climb.

Gliders can now reach altitudes of over 40,000 feet, stay in the air for over 50 hours, and carry out flights of hundreds of miles. The flying of sailplanes apart from being an exhilarating sport has made important contributions to aeronautical and meteorological research.

Golf.

Golf, a game of great antiquity, originated in Scotland, and is now widely popular in many countries. It consists of using a set of clubs with which to play a small white ball over a cross-country course of eighteen holes. Each hole will be several hundred yards long, and will have its fixed starting-point and its finish with an actual hole in the ground, the object being to complete the course, which will be several miles long, in as few strokes as possible.

The playing of each hole falls into three sections, driving, approaching, and putting. The starting-point will be a flat piece of ground on which the player will "tee up" his ball on a small rubber peg, or "tee," which he will carry round with him. He will then hit the ball towards the hole, concentrating on achieving distance. From the tee to near the hole is the "fairway," which will consist of fairly smooth ground, not entirely devoid of natural obstacles, and probably containing some sand traps, or "bunkers." On each side of the fairway is the "rough," which may consist of long grass, shrubs, woods, or even roads. The player will continue to play his ball towards the hole, concentrating now chiefly on direction. On the fairway or off it, he should always play his ball where it lies, but, should it be quite unplayable, or even lost, he may drop it or a new one, and pay a stroke penalty for the privilege. The actual hole will be on the "green," a rough circle of exceptionally well tended grass, and, once on it, the player will cover the last few yards by the more delicate art of "putting."

There are many different types of club, players being limited to fourteen. The shafts are generally steel, the striking surfaces being iron or, in the case of drivers, wood. The different "irons" have numbers, but golf clubs used to have special names, often descriptive of their functions, for instance, lofter, cleek, mashie, niblick, and even blaster. Originally, most golf courses were by the sea, and these were called "links," a term now loosely applied to any course.

There are two actual methods of competitive play, match play and medal play. Match play is by holes, a player completing any hole in fewer strokes than his opponent winning that hole. Once a player leads by more holes than there are still to play, the game finishes, the victory being by X and Y, where X is the number of holes he is "up," and Y the lesser number of unplayed holes. When a player leads by the same number of holes as there are still to play he is said to be "dormy" so many. Opponents level after eighteen holes proceed to the first hole, and play on until one is one hole up, when he is said to have won at the 19th, 20th, or whatever it may be. Some important match-play events are over 36 holes, or two complete rounds. Medal play is simply stroke play, the result depending on the number of strokes needed to complete the course. This demands a higher level of consistency, for one bad spell can ruin the total, whereas, in match play, it may cost only one hole. In play after the initial drive, the player farthest from the hole normally plays before his opponent.

In match-play championships and tournaments players are drawn against each other, the winners going on to the next round, and so on up to the final. In medal-play events players go round in pairs, but each is, of course, playing against the whole field. Team matches consist of singles and foursomes, in which the partners play shots in turn. Other, less-formal forms of golf are four-ball foursomes, in which each player plays his own ball; best-ball foursomes, in which both partners drive, but, thereafter, play in turn only at the most successfully driven ball; and th somes, in which each player plays for him against the others. During a match, a pl must not receive advice from anyone except "caddie," if he has one, the caddie being attendant who makes a profession of carr golfers' clubs round.

Every course has its "bogey" and "p figures, these being scores, with par represen the higher standard that a first-class player m achieve for the course. By assessing a memb own scores against these figures, clubs allocate a handicap which indicates the play standard. There are many minor competit in which golfers play, not on level terms, but f their handicaps, which also serve as a perpe incentive to players to improve their game, therefore their handicaps. The possession handicap also makes it easier for players arrange even matches with strangers. Handi are subject to alteration as a player's stand changes, and such alterations may be in ei direction. The operation of the handicap in takes the form of strokes deducted from the ac score at certain holes, in accordance with arrangements in force at any particular club.

Golf offers a tremendous number of competit of all standards, as well as championships team matches. Probably of the four most portant individual championships are the Br Open, the British Amateur, the American O and the American Amateur. These are l established, but the two major international t events are quite new. They are the World C open to teams of two professionals from country, and the Eisenhower Cup, for team four amateurs, the three best scores count from any country. Other, much older in national team events include the Ryder, Wal and Curtis Cups, which are contests betw Britain and the United States for professio amateurs, and women, respectively; though interesting to note that the actual inscriptio the Curtis Cup indicates that this trophy is o to women golfers of any country.

Golf is ruled by the Royal and Ancient Clu St. Andrews, Scotland, which is recognised over the world as the game's headquarters. T was an unusual illustration of this widesp recognition when the Eisenhower Cup competi was instituted by the United States in 1958, at the special request of the American organi the first meeting took place, not in the Un States, but at St. Andrews. The Royal Ancient Club makes the rules of golf, but t are generally supplemented by local rules in f at particular clubs.

The popular expression "rub of the gre used to describe an unexpected and unavoid mischance, comes from golf, where it is used w a putt fails to take the expected line because slight flaw in the normally perfect turf of green.

Gymnastics.

Gymnastics is a system of exercising with paratus, and also a competitive sport, the c items of apparatus used being the horizontal the parallel bars, rings, ropes, ladders, and vaulting horse. The horizontal bar, the par bars, and the rings can all be used for sin exercises, some being fast swings and others movements requiring considerable stren Strength and swinging also come into la exercises; and the rope, which can be climbe several different ways, is a simple form of paratus that demands, and will develop, stren The horse can be used for a variety of vault either the lengthways or sideways position, still others are possible when pommels are fi to it. In addition to those who specialis gymnastics, many sportsmen of various k regularly attend gymnastic classes as part of t training for their own particular activities.

The Trampoline, which is something like a l and very springy mattress, and which has been used by circus and stage acrobats, has been accepted as a piece of gymnastic appara Gymnasts, divers and other sportsmen use l

aining; it is also used in the Services in the aining of commandos and parachutists. There e trampoline competitions and championships, which gymnasts perform many of the acrobatic ats normally performed on the floor.

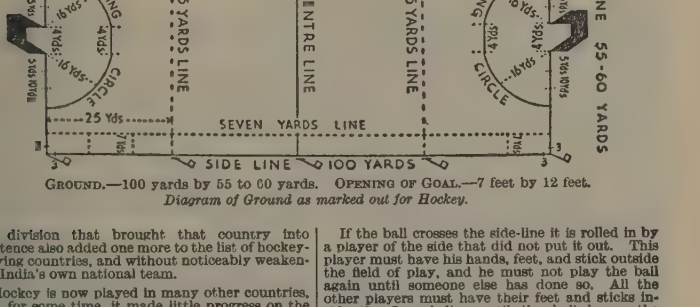
ockey.

Hockey originated about three-quarters of a ntury ago as a game confined to Britain, but ith rules that varied in each of the home untries. However, in 1900, England, Ireland, d Wales combined to form the International ockey Board, with a view to formulating rules at would apply wherever the game was played, d, two years later, Scotland joined the alliance. e game was also taken up with terrific enthus-sm in India, and Indian players became, and main, the best players in the world. Their thusiasm extended to what is now Pakistan, so

In play, the ball must be propelled only by the stick, and it must not be stopped with any part of the body except the hand, in which case it must only be stopped, and not caught or knocked forward. These prohibitions, however, do not apply to goalkeepers, who may stop the ball with any part of their body, and also kick it, when in their circle. No part of a player's stick must be raised above the shoulder either at the beginning or end of a stroke, or to stop the ball. Hitting the ball in the air and scooping it are allowed, but deliberate undercutting is not, and umpires can penalise any hit which they judge to be dangerous. Interfering with an opponent's stick, running between an opponent and the ball; and charging or other bodily contact are not allowed. Players must not tackle from the left unless they can play the ball without touching the opponent or his stick.

A player is "offside" if there are fewer than three opponents between him and the goal-line, unless he is in his own half, or unless a team-mate playing the ball is nearer to the goal-line than he is. A player who is offside is put onside if an opponent plays the ball, but not if the ball merely touches or glances off the opponent. Players who are offside are not penalised if they do not interfere with the play.



GROUND.—100 yards by 55 to 60 yards. OPENING OF GOAL.—7 feet by 12 feet.
Diagram of Ground as marked out for Hockey.

e division that brought that country into istence also added one more to the list of hockey-aying countries, and without noticeably weaken-g India's own national team.

Hockey is now played in many other countries, t, for some time, it made little progress on the ontinent. Eventually, though, it was tried, ked, and adopted in a number of European ountries, and one of these, the Netherlands, has w established a right to a place alongside ndia, Pakistan, and Britain as the game's top yer. Hockey has, and has long had, Olympic ames status.

Hockey is played eleven-aside on a pitch marked t as in the accompanying diagram, the normal ositions of the players being a goalkeeper, two ull-backs, three half-backs, and five forwards, xactly as in Association Football (*q.v.*). The hite ball can be either sewn, as is a cricket ball, r seamless, and it must weigh from 5½ to 5½ nces. Sticks must weigh from 12 to 28 ounces, nd have a handle that can be passed through a ng with an inside diameter of 2 inches. They ave a striking surface on the left side only, ft-handed sticks not being permitted. A game onsists of two 35-minute halves, unless the aptains have agreed on a shorter period.

The game is started, and restarted after half-me and after a goal, by a bully at the centre of he ground. The players bullying stand facing he side-line, each with his own goal on his right. ach taps the ground between the ball and his wn goal and his opponent's stick over the ball hree times alternately, after which one of them ust play the ball. At any bully, all the other layers must be 5 yards from the ball, and etween it and their own goal.

If the ball crosses the side-line it is rolled in by a player of the side that did not put it out. This player must have his hands, feet, and stick outside the field of play, and he must not play the ball again until someone else has done so. All the other players must have their feet and sticks inside the 7-yard line until the ball leaves the roller's hand.

If the ball is sent across the goal-line wide of the goal by an attacker, or, unintentionally, by a defender who is more than 25 yards from the goal-line, the restart is by a bully on the 25-yard line. If it is hit behind unintentionally by a defender who is within 25 yards of the goal-line, a corner is awarded to the attacking side. If it is hit behind intentionally by a defender from any part of the ground, a short, or penalty, corner is awarded to the attacking side. A corner is a hit from a point on either the goal-line or the side-line within 3 yards of the corner flag, while a short corner is a hit from a point on the goal-line 10 yards from the nearer goal-post. At a corner all the defenders must be behind the goal-line, and all the attackers outside the circle. When the corner hit comes into the circle, attackers are not allowed to take a first-time shot, but must first stop the ball or slow it down. At no time during the game can a goal be scored unless it was hit from inside the circle.

Penalties for infringements outside the circles are generally free hits. Penalties for infringements inside the circle by defenders are short corners, unless they have been deliberately committed to prevent a goal, or have, in fact, prevented a goal, in which cases a penalty bully is awarded. In extreme cases, both short corners and penalty bullies can be awarded for offences anywhere behind the 25-yard line.

In 1963 the penalty stroke was introduced. This replaced the penalty bully, a duel between the offender and one opponent, with all the other players beyond the 25-yard line, that started with a bully 5 yards from the centre of the goal and continued until either a goal was scored or the ball was hit behind the attacker or out of the circle by the defender. If it was hit behind by the defender, the bully was restarted. This was a novel feature, but a not altogether satisfactory one, as the duel was sometimes protracted. The penalty stroke, if less spectacular, is also less complicated.

A game is controlled by two umpires, each of whom takes one half of the field and one complete side-line. Substitutes are not permitted in hockey.

Hockey is entirely an amateur game. Almost every match is a friendly, for, in Britain, there are no leagues and only a very few rather specialised cup competitions. There are, however, a great many representative games, from county matches up to internationals.

A major feature of the hockey season, which normally lasts from October until March, is the end-of-season Easter Hockey Festival. There are actually several festivals, most of them taking place at seaside resorts. Teams go to them from many different areas, including the Continent, and play three or four matches in four days against opponents whom they would not normally meet. Six-aside tournaments also take place occasionally during the season.

Hurling.

Hurling, which might loosely be called the Irish brand of Hockey (*q.v.*), is played fifteen-aside, and has been described as the fastest game using a ball in the world. The ball, called the "slitter," and the sticks, called "hurleys," bear some resemblance to Hockey's ball and sticks, but nothing like Hockey's "sticks" rule applies. The slitter may be hit at any height, and with either side of the hurley, and it may be kicked or caught, though it must not be carried more than three steps, nor picked up off the ground. There is no offside, apart from the fact that attackers must not enter the parallelogram marked out near the goal ahead of the slitter. The goals have uprights that are extended above the cross-bar, and scoring is by goals, under the bar, and points, over the bar, a goal equalling three points. There is a good deal of bodily contact, and substitutes are permitted for injured players.

Hurling, rarely played by anyone who is not Irish, but often played by Irishmen outside Ireland, is of great antiquity, and the English authorities in Ireland first tried to suppress it six hundred years ago. It was kept alive, however, and it is very much alive to-day. To Irishmen, Hurling and Gaelic Football (*q.v.*) are symbols of nationalism and patriotism. They are governed by the Gaelic Athletic Association, which has a rule that states: "Any member who plays or encourages Rugby, Association Football, Hockey or Cricket by that very fact incurs immediate suspension from membership of the Association."

A form of Hurling with slightly different rules, called Shinty, is still preserved in another Celtic country, Scotland.

Korfball

Korfball is a team game with several unique features, the most striking being that it is a mixed game, a team consisting of twelve players—men and six women. The game resem Basketball (*q.v.*) in some ways, the goals, w are 11½ feet high, and the scoring of goals b similar. It can be played on any firm sur the pitch measuring 300 feet by 133 feet, th a smaller pitch can be used, provided that le and width are reduced in proportion. The p is divided into three sections, and players dc move from one sector to another during ac play. They must, however, change to anc zone after every two goals. This encourage round attacking and defensive ability, and en that, even in a one-sided match, every pl gets a fair share of the game. Four players each team play in each section, and players al mark opponents of their own sex. Players mus run with the ball which is advanced purel passing. There is no tackling, and the ball only pass from one team to the other by i ception. Players may not score if there i opponent within arm's length. A game last 90 minutes, divided into two halves.

Korfball originated in the Netherlands, whe was first played in 1902. It spread to Belgiu 1927, and reached England in 1947. There International Board, on which the Netherla Belgium, and England are represented. I national inter-club matches are a regular fes of the game. Though really a winter g Korfball is actually played all the year ro the international games between clubs from three Korfball countries taking place during summer.

Lacrosse.

Lacrosse, which originated from a game pl by the Red Indians, was introduced into Eng from Canada in 1867, and has been played ever since.

Basically, it is, perhaps, the simplest o field team games. The object is the prope of a rubber ball through goals 6 feet wide a feet high with a wooden "crosse" not more a foot wide at its widest point, where there "mesh" of strings. The goals are from 9 110 yards apart, but play can take place be them, for there are no boundaries to the p except the natural borders of the field, unless captains have agreed otherwise. The only required are the centre circle, the goal-lines, the goal-creases.

In England teams consist of twelve pla but in Canada and the United States the nu was reduced to ten some years ago. Pla line up right down the field, instead of onl their own half, and there is no offside, except no attacker may enter the goal-crease before ball. Should a player leave the field thr injury, his opponents must also withdraw a

A game consists of four 20-minute periods, the captains can agree to vary this, either to 45-minute halves or otherwise. The gam started or re-started after a stoppage by player from each side "facing" by placing ball on the ground between the backs of the crosses, and then drawing them apart, which the ball is in play. It can then be adva by running with it on the crosse, throwing it the crosse, or kicking it, though no goal, excep "own goal," can be scored by a kick. Only goalkeeper, who can deflect the ball with his h but not catch or throw it, may handle the Players can shoulder opponents when tryin get the ball off the ground, and "body che them by simply standing in front of ther impede them. A player can also check opponent's crosse with his own crosse if opponent has the ball. A foul is penalised giving the non-offending player a "free positi which means that he is given the ball, and game is then re-started.

Lacrosse demands speed and stamina, a high level of skill demands practice, but it is hard for a beginner to grasp the main objec master the comparatively simple rules.

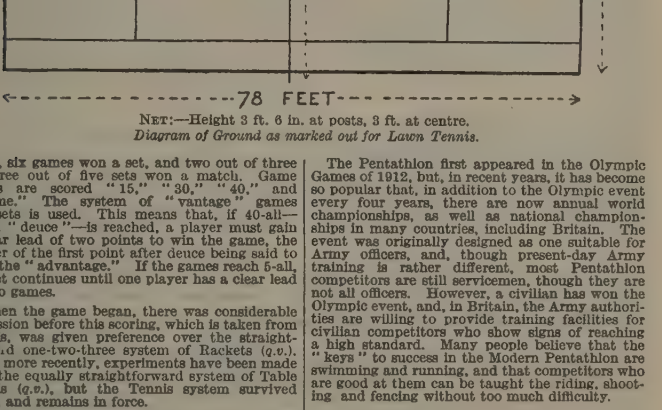
It is interesting to note that Lacrosse, w can be one of the roughest of all games, has

made a suitable game for women by very simple measures, such as the elimination of the body check; and that there are now more women playing than there are men.

Lawn Tennis.

Originally called Sphairistike—or "Sticky" by those who disliked it—Lawn Tennis was invented in the seventies of the last century as a simplified, outdoor version of Real Tennis (q.v.), using a net, but no walls. It is now far more widely played than the parent game, being popular almost all over the world. As its name implies, it was originally intended to be played on grass, but it is now also played on hard courts of various surfaces, and indoors on wood.

The court is as shown in the accompanying diagram, the outer long boundary lines being the limitations for doubles, and those parallel to them being the boundaries for singles. Both server and receiver score, four points making a



NET:—Height 3 ft. 6 in. at posts, 3 ft. at centre.
Diagram of Ground as marked out for Lawn Tennis.

game, six games won a set, and two out of three or three out of five sets won a match. Game points are scored "15," "30," "40," and "Game." The system of "vantage" games and sets is used. This means that, if 40-all—called "deuce"—is reached, a player must gain a clear lead of two points to win the game, the winner of the first point after deuce being said to have the "advantage." If the games reach 5-all, the set continues until one player has a clear lead of two games.

When the game began, there was considerable discussion before this scoring, which is taken from Tennis, was given preference over the straightforward one-two-three system of Rackets (q.v.). Much more recently, experiments have been made with the equally straightforward system of Table Tennis (q.v.), but the Tennis system survived these, and remains in force.

Service is almost invariably overhand, and the receiver plays the service after one bounce. Thereafter, strokes may be "ground" strokes, played after one bounce, or volleys, played before any bounce. In doubles, either partner may play the ball, but each must serve in turn.

In addition to being played by thousands of people, Lawn Tennis attracts large crowds of spectators. The big annual tournaments, such as Wimbledon, Forest Hills, and Paris, are amongst the major sporting events of the year; as are the Davis Cup competition, open to teams of men from every country in the world, and the Wightman Cup, a women's contest between Britain and the United States. All these events are amateur; but the game also has a top layer of professionals, whose annual world tours are a great attraction.

Marbles.

See Old English Games and Customs.

Modern Pentathlon.

Imagine a king's messenger riding with an important dispatch, and being hotly pursued. His horse is shot, and he has to engage his pursuers, first with his revolver, and then with the sword. Eventually, he breaks away, swims a river, and finishes his journey on foot and running.

That is the "plot" on which is based one of the most interesting, exciting, and testing of all sporting events, the Modern Pentathlon. Often wrongly thought to be a part of Athletics, the Pentathlon is a separate sport, but one that actually consists of five different sports: the five activities, in fact, of the king's messenger in the story, riding, revolver shooting, fencing, swimming, and running. True, the Pentathlon competitor does not have to carry them out one after the other, but he does have to take part in them in that order, one on each of five successive days, both riding and running being across country, the riding on a horse strange to him.

The Pentathlon first appeared in the Olympic Games of 1912, but, in recent years, it has become so popular that, in addition to the Olympic event every four years, there are now annual world championships, as well as national championships in many countries, including Britain. The event was originally designed as one suitable for Army officers, and, though present-day Army training is rather different, most Pentathlon competitors are still servicemen, though they are not all officers. However, a civilian has won the Olympic event, and, in Britain, the Army authorities are willing to provide training facilities for civilian competitors who show signs of reaching a high standard. Many people believe that the "keys" to success in the Modern Pentathlon are swimming and running, and that competitors who are good at them can be taught the riding, shooting and fencing without too much difficulty.

Mountaineering.

Among famous peaks, Mont Blanc was first conquered in 1786, the Jungfrau in 1811, and the Wetterhorn in 1854. By then, Mountaineering was becoming organised, and there were systematic assaults on the Alps; in Norway, the Caucasus, and Corsica; in the Rockies and the Andes; in Japan, New Zealand, and Kenya; and, of course, in the Himalayas, where over thirty years passed between the first assault on Everest and its conquest in 1953. There are still unconquered peaks in the Himalayas, but it is not only first ascents that interest the mountaineer; he can find exciting climbing in many parts of the world.

The way to master Mountaineering is to accompany and watch experts. Perfect physical and nervous fitness is essential, as is a detailed knowledge of snow, ice, avalanches, glaciers, crevasses, and cornices, and of the different

techniques of ascending, descending, and traversing. Also to be learned is step-cutting, which is hard manual labour carried out under difficult conditions, conditions that may make perfect workmanship literally a matter of life or death. Clothing, properly nailed boots, ropes, ice axes, knives, maps, compasses, medical supplies, must be of the best, and yet, at the same time, light.

Mountaineering is generally taken to mean snow and ice climbing, but allied to it is Rock-climbing, which demands the same perfect physical and nervous condition, and, in place of knowledge of snow and ice, knowledge of several very different kinds of rock. Ascending, descending, and traversing all apply, and so do ropes, and the rock-climber should, in fact, be something of a knot expert. Light, rope-soled shoes replace the mountaineer's nailed boots. Skye is a favourite haunt of rock-climbers, and, in view of what might justifiably be called the antiquity of climbing, it is surprising to note that the highest peak in Skye, Sgurr Alasdair, was not conquered until 1873.

The Mountaineering Association, 102A Westbourne Grove, London, W.2, runs training schools for climbers at all stages in Britain and abroad; and also runs evening classes on rock climbing in conjunction with education authorities. The Holiday Fellowship organises climbing tours in the Highlands of Scotland, climbing many well-known mountains. In Scotland useful addresses are the Scottish Mountaineering Club, 406 Sauchiehall Street, Glasgow, C.2, and the Junior Mountaineering Club, 28 Croftmont Avenue, Croftfoot, Glasgow, S.4. At the White Hall Centre for Open Country Pursuits, Manchester Road, near Buxton, the Derbyshire County Council hold courses for those between 13 and 20 plus on hillcraft, rock climbing, camping, ski-ing, and canoeing. The Outward Bound Trust, 123 Victoria Street, London, S.W.1, runs schools in Wales and the Lake District to train boys—with a few courses for girls—how to face hazards and hardships of all kinds on mountains and sea.

Music.

One of the most novel changes of the last generation or so has been the widespread diffusion of music not only in this country but all over the world. Twenty or thirty years ago it might have been necessary to travel a long way to hear the performance of a classical musical work; and the opportunity of doing so was only occasional. We can now have a constant flow of such music from wireless and record player. Several things follow from this change. Leisure has been transformed by " high fidelity " and the long-playing record. People listen more easily and frequently than they read; and it is music, rather than literature, which is at the centre of culture. Access to good music does not depend upon training and application to the same extent as access to good literature. It is easier for the tired person to enjoy music than a serious book. " Where the library shelves used to stand," says a commentator, " there are now the record albums, row upon proud and esoteric row." The listener may well be submerged, by the easy flow of music of vastly different kinds; but there is an opportunity for the discerning listener to compare and to select from the music of the different centuries, to study the difference between the classical and romantic masters, the emergence of modern orchestration, choral music, chamber music, opera, and oratorio. We may go on to study other aspects—the study of the personality of the composers; the relation between their work and the problems of the times; knowledge of the different instruments; and how to enjoy reading a musical score. By this means the listener can combine refreshment of spirit with the delights of exercising skills of various kinds.

All through the summer, all over the country there are opportunities for music lovers, whether active musicians or not, to spend a holiday together and pursue some aspect of music. The reader will probably be surprised to learn that there are nearly one hundred such summer schools each year, some for the week-end, others for a week or fortnight. The Rural Music Schools Association at Hitchen, Herts, would help enquirers for particulars. A glance at the annual list shows how wide are the subjects offered: madrigal and other singing, recorder playing, orchestral and chamber music, Russian music, 18th-century music, discussion for wind teachers, the making of musical instruments. These summer schools are in addition to the Music Festivals held at Edinburgh, Bath, Cheltenham, and other places, not forgetting the Three Choirs Festival in the West (British Federation of Music Festivals, 106 Gloucester Place, London, W.1). Details of the various continental festivals can be obtained from the European Association of Music Festivals, 122 rue de Lausanne, Geneva, or 82 Beauchamp Place, London, S.W.3.

Your local public library probably has a music library. The National Operatic and Dramatic Association, 1 Crestfield Street, London, W.C.1, has a library of musical scores and dramatic works. The National Federation of Music Societies publishes a catalogue with practical details of some 500 choral works and assists music societies with advice, information, and in other ways; its address is 4 St. James's Square, London, W.C.1. The Workers Music Association provides opportunities for developing musical instincts and tastes, believing that genuine art moves people to work for the betterment of society. It organises classes, lectures, and week-end and summer schools; also offers correspondence courses in Harmony, Counterpoint, and Orchestration. Its address is 17 Bishops Bridge Road, London, W.2.

Many local authorities have record departments in their local libraries. The Central Gramophone Library (88 Russell Square, London W.C.1) has a circulating library of records which are available to adult education lecturers, music and gramophone societies and to hospitals and prisons. Those interested in forming a gramophone society should get into touch with the National Federation of Gramophone Societies. The British Institute of Recorded Sound, 38 Russell Square, London, W.C.1 contains the national archives of gramophone records and other sound-recordings and is the national centre for information and documents.

Natural History and Field Studies.

There are nine Field Centres in England and Wales, at:

- Juniper Hall, Dorking, Surrey.
- Flatford Mill, East Bergholt, near Colchester, Essex.
- Malham Tarn, near Settle, Yorkshire.
- Dale Fort, Haverfordwest, Pembrokeshire (including Skokholm Bird Sanctuary).
- Preston Montford, near Shrewsbury, Shropshire.
- Slapton Ley, Slapton, Kingsbridge, Devonshire.
- Orielton, near Pembroke, S. Wales.
- Nettlecombe Court, Williton, Taunton, Somerset.
- Rhyd-y-Creua, Betws-y-Coed, Caernarvonshire.

The nine centres have been set up by the Field Studies Council in localities selected for their ecological features and for their geological, geographical, archaeological, and artistic interest. Working facilities and expert guidance are available at the Field Centres to all who have a serious interest in the countryside—whether as amateur naturalists or as students or as research workers. They are not reserved for the academic student only. The Council want to encourage and help the beginner and the ordinary person who has an interest in some branch of natural history and wishes to learn of this or allied subjects. The Centres are staffed and suitably equipped to provide residential accommodation and working facilities for numbers ranging up to about sixty persons. Thus field workers enjoy the skilled guidance of the staff, local contacts and information, benches, space, tools, maps and records, with something of the intellectual and social life of a small residential college. There are special courses for amateurs, and some of these are less formal than the word " course " suggests. The subjects vary wide

including bird study, land structure and scenery, and outdoor painting and sketching.

Juniper Hall, amidst the beautiful chalk hills of the North Downs, is well situated for almost every kind of field study. Flatford Mill is at the head of the Stour estuary, in the countryside of Constable and Gainsborough. The Stour, with its tributary streams, its mill pools and cattle ponds and dykes, provides excellent scope for water biology. Malham Tarn Centre is on the shore of the tarn on the limestone uplands at the head of Airedale in the Yorkshire Pennines. Here is the rich flora of well-drained pastures, screes, and limestone. The tarn itself supports an abundant fauna of invertebrates and fish. Dale Fort at the tip of a narrow peninsula guards the approach to Milford Haven. The flowers on the cliffs in May and June are the envy of the rock gardener. The opportunities for the marine biologist are unsurpassed. But there is no specialisation to the exclusion of any of the many subjects that can advantageously be studied. The Bird Observatory on Skokholm Island is a part of Dale Fort Field Centre, and here work on birds has pride of place. Guillemots and razorbills breed on the rocks, and puffins and shearwaters burrow in the edges of the plateau. Preston Montford lies on the banks of the Severn four miles west of Shrewsbury, where geological formations are displayed conveniently for study. In the North Shropshire plain is scope for the study, too long neglected, of the ecology of ordinary English farming country that man has influenced for more than 2,000 years. There are numerous localities of archaeological interest, including the Roman town of Viroconium. At Slapton Ley the 300 acres of Slapton Nature Reserve offer ample scope for interest in most branches of Natural History. The Ley is separated from the sea by a shingle bank. There are moorland and bog: slate and limestone cliffs; lake shores and beaches; and woodlands. Enquiries can be made to the Field Studies Council, Ravensmead, Keston, Kent.

Everyone who *wants* to work in the field can find something useful to do, whatever his natural bent and his training, since the range of research is vast and the problems diverse, with such varying degrees of difficulty. This opportunity has been greatly extended by the increasing importance of ecology, which is a distinctive point of view in the approach to field biology. In its most general sense ecology may be defined as the study of plants and animals *in their natural homes*. The growing popularity of the subject in this country represents a breakaway from the confinement of serious work in biology to the laboratory and museum. These are still, of course, absolutely necessary, but the primary place in which to work at ecology is the field.

Bird-watching. The pleasure of bird-song and the sight of their activities is a common one for most of us. From this point many are prompted to make a closer study of birds and their habits. To get the most pleasure it is a great advantage to turn for advice to those who have had a wide experience. The enthusiast will thus become equipped with some knowledge of methods of bird-watching, how to make field notes and keep records, hides, identification, tables of family likeness, migration, sanctuaries, bird photography, and the structure of the bird.

Bird-watching is not confined to those who live in the country. London has probably more bird-watchers than any other part of Britain. With the possible exception of the parish of Selborne in Hampshire, immortalised by Gilbert White, London, has the longest continuous history of ornithological observation in the British Isles. Groups of enthusiastic naturalists have collected a mass of detail about wild birds and their habits in London. The list of London birds is not only extraordinarily large but also contains many rarities and many birds of great scientific interest, like the black redstart and the little ringed plover. There are also special London problems, like the roosting of starlings in central London and the origin of this starling population. The reservoirs and the river, the commons and woods and parkland around London offer pleasant places for observation. The London Natural History Society (headquarters, the Natural History Museum, Cromwell Road, S.W.7) has, as its chief object, the study and enjoyment of natural history in the London area.

Visiting Nature Reserves. The Nature Conservancy welcome visitors to National Nature Reserves within the limits set by the Conservancy's own responsibilities towards these lands and their plants and wild life. The Reserves are maintained on behalf of the nation to conserve their natural fauna and flora, and so far as possible to enhance their interest and value to science. As far as possible the Reserves are accessible for the use and enjoyment of all who are prepared to respect the necessity for handing them on unimpaired to future generations and for avoiding interference with scientific work. Many Reserves are accessible without formality; elsewhere a permit is required. A list of the Reserves is obtainable from the Conservancy, 19 Belgrave Square, London, S.W.1, or in Scotland from 12 Hope Terrace, Edinburgh, 9. There are some eighty National Nature Reserves. Among the extremely small reserves is, for example, the North Fen Reserve, 4 miles S.S.W. of Ambleside showing a vegetational succession of open water rich in mineral salts to fen, carr, and bog. The largest in Britain is the Cairngorms in Scotland, of nearly 40,000 acres, with fauna rich in variety of species from wild cats to golden eagle and a diverse flora, which includes the arctic-alpine plants of the corries, screes, and exposed summits.

The Council of Nature. If you are interested in any aspect of natural history—for example in plants, birds, rocks, insects, trees, butterflies, or natural history photography—you will have no difficulty in finding the address of your local history society, of which there are a very large number. The local public library would doubtless give you the address you want, or you could enquire from the Council of Nature, 41 Queen's Gate, London, S.W.7, to which over two hundred organisations belong. These include the Royal Society for the Protection of Birds, which has upwards of 9,000 members and runs the Junior Bird Recorders' Club for young people interested in bird-watching. The Council links amateur and specialist in the study of natural history and the conservation of wild life. It has an Intelligence Unit which is ready to deal with requests for information on field natural history in the United Kingdom. The Film Officer of the Unit will advise amateur still and ciné photographers on all aspects of natural history photography. He will also be able to advise on what natural history films are available and on likely sources for photographs of any British wild animal or plant.

Netball.

Netball, which is played exclusively by women, is similar to Basketball (*q.v.*), but it is played seven-aside, does not allow substitutes, and the goals have no backboards. It is almost always played outdoors on asphalt or grass.

Nine Men's Morris. *See* Old English Games and Customs.

Old English Games and Customs.

The story of England had its beginnings a very long time ago, and many of England's present-day customs, recreations, sports, and games can be traced far back in that story. Some, of course, have undergone very considerable changes, but the links with the past are still clear.

On 1 May, for instance, girls still awake in some villages to the realisation that they are to be May Queens, and to reign for a day, though they may not realise that they are preserving a custom that can point to origins in the days of the Druids, and that, in Tudor times, would have sent them and their fellow villagers out to spend the preceding night in the woods, gathering branches of trees and flowers with which to decorate their houses. Maypoles and morris dancers also belonged to May Day, and they can still be seen in England, and not only on that day.

More local, even quainter, but equally traditional is the trial for the Dunmow Flitch of Bacon in the village of Dunmow in Essex. The original conditions offer this award to any married couple who will go to the twelfth-century Augustinian priory, and there kneel on two sharp-pointed stones and swear that they have neither quarrelled nor repented of their marriage within a year and a day of its celebration. This award has lasted into modern times, not annually, it is true; but then it never was given annually, for it was instituted in 1244, and first claimed in 1445.

One annual event that is as traditional as it is strenuous in the Whit Monday cheese-chase at the village of Brockworth, near Gloucester. Records of this go back to the days of the Stuarts, for that was when they started to keep records of a custom that was already old then: so old that its origins are unknown, though they had to do with the villagers' cattle-grazing rights. A massive round cheese is rolled down nearby Coopers Hill, which has a gradient of one in four throughout its 150 yards; and, with a certain amount of risk to life and limb, the chasers tear down after it, the cheese being the prize for whoever catches it. Sometimes, the cheese hits a bump, and literally leaps out of reach over the hedge at the bottom of the hill, but the chase continues, the prize going to the first pursuer to reach the hedge, where "catchers" wait to halt the headlong rush of the runners. Despite the obvious dangers, the records to date mention nothing worse than a sprained ankle.

This brings us to sports and games: and, though today's most popular game, Football, is, in anything like its present form a comparatively recent growth, it can perhaps claim some relationship with Harpastum and Campball, which existed before the Norman Conquest; and it was one of the popular recreations banned in the interests of Archery. The football of those and later days, however, took the form of struggles between whole villages, the players battling *en masse* over a cross-country course of several miles. People past whose houses the battle was likely to rage prudently barred and shuttered all windows and doors, awaited the cessation of hostilities with anxiety, and probably helped to push this particular custom into oblivion.

The oldest English games are old indeed, and Cricket, too, had remote ancestors, from which the descent to today can be traced more directly. They included Bat and Trap, Creag, Cat and Dog, and Rounders. In Bat and Trap, the batsman hit a ball released from a trap between two posts. His opponent rolled it back underarm at the trap flap. If he knocked it down, the batsman was out: if not, the batsman scored one run and had another hit. This game is still played in Kent. Creag, which was played at the time of Edward II, used a curved stick, called a "cryc," as a bat, and a tree-stump as a wicket. Cat and Dog, which came later, was a game for three, two batsmen defending holes 13 yards apart, and trying to hit away the piece of wood that the third player aimed at the holes, the bats being the "dogs" and the piece of wood the "cat." It is worth noting that Baseball's accepted ancestors are games called One Old Cat and Two Old Cat, which clearly indicates a common origin for Cricket and Baseball. Some of the games in Cricket's ancestry remained popular after Cricket arrived, and Rounders is still a popular children's game.

The beginning of Athletics can also be found in old England. Putting the weight and casting the bar, a forerunner of throwing the hammer, were popular with the courtiers in Tudor days, while other events, including javelin throwing, were practised by ordinary people of the same period. Later, the early hammer throwing spread beyond the Court, and was even attempted by women, which modern hammer throwing is not.

Tournaments and jousts were popular from the Middle Ages until Tudor times. These were combats between mounted men, a joust being single combat, while a tournament involved many contestants. They were succeeded by dismounted combats, which still take place today in the sport of Fencing. Those taking part in tournaments and jousts were required to swear an oath to the effect that they were competing purely for sport; and those taking part in the Olympic Games and certain other big sporting meetings to-day swear an almost identical oath. Somewhat similar to jousting, but not restricted as jousting was, to the nobility, was Tilting at the Quintain, which was practised both mounted and on foot, and in which a lance was thrust at a wooden target, which, if not struck accurately, swung round and struck the tilter.

Other old games, clearly the ancestors of modern ones, included Handball, which became Fives, but which is still handball in the United States; Battledore and Shuttlecock, still a children's game, but now developed by adults into Badminton; and Shovelboard, an elaborate game, for the nobility, which consisted of sliding weights down a long table marked with lines, a game which is certainly a forerunner of Shove-Halfpenny. Another probable ancestor of Shove Ha'penny was Squails, in which a coin was placed in the centre of a round table, and players tried to push their "squails," or discs, as close to the coin as possible, distances being measured by an instrument called a "swoggle." Also known as Skayles and Keels, this game appeared in the sixteenth century, lasted into the nineteenth century, and, under the name of Keels, achieved a poetic mention in Sidney's "Arcadia."

Archery. Archery goes back hundreds of years to the days when the bow was the chief weapon of war, and, because of that, practice shooting and contests were officially encouraged: encouraged, in fact, to the extent that other popular recreations, like Football, Quoits, and Bowls, that might have interfered with it were banned, though the bans were always largely ignored. Eventually, the bow disappeared from the battlefields, but, to this day, it has remained popular as a means of recreation and sport. Throughout the centuries, archery contests were generally of three kinds: shooting at a mark, or target; shooting purely for distance, though this was more popular abroad, in countries like Turkey than in Britain; and shooting at "rovers," which two or three archers would cover a cross-country course, taking it in turns to select a mark at which to shoot. To-day, archery, which retains enough of tradition in its terminology to remind the archer that he is following in a very long line, consists of shooting at a target containing rings coloured, going from the centre outwards, gold, red, blue, black, and white, the values being respectively, nine, seven, five, three, and one.

Knur and Spell. Knur and Spell belongs to Lancashire and Yorkshire, and originated in children's game called Trap and Ball. The player uses a wooden club, the striking end of which is called the "pommel," is shaped something like a bottle, though it has a flat hitting surface, with which to hit a small ball, which he himself releases from a trap by means of a trigger. The ball, which is the "knur," weighs ½ ounce, measures one inch in diameter, and was originally wooden, though, later, porcelain was used. The trap, or the "spell," and consists of a small brass cup with a strong spring, which is kept down by the trigger. The firing of the spell is an elaborate process requiring the use of a spirit level, and, when it is in position, a player is allowed 10 minutes to adjust the tension of the spring. Players generally have their own spells. Each player has five consecutive hits, or "rises," and scores one point for every 20 yards covered.

Marbles. Marbles is supposed to have been played in ancient Egypt, but its popularity, with adults as well as children, in the England of the Middle Ages entitles it to count as an old English game. Marbles are often made of clay, but better ones are glass, and the best are pure marble. These are called "alleys," or "alley tawns." There are several games of marbles, but they all involve the aiming of a marble at a target, which may be another marble or an opening, by bowling or "shooting" it along the ground. In shooting

he marble is held between the thumb and fore-inger, with the knuckle of the forefinger on the round, and is then flicked away.

Perhaps the best-known game is Ring Taw, in vhich players shoot from one circle at marbles laced in another about 6 feet away. Fortifica-ions and Increase Pound use concentric circles. layers shooting at marbles in each circle in turn. Three Holes and Handers involve shooting at holes n the ground; Arch Board or Bridge, at arches n an upright board; and Die Shot, at another narble on which a numbered die is balanced.

Nine Men's Morris. Nine Men's Morris is a ourteenth-century game for two, usually played utdoors on a diagram marked on the ground, ut sometimes played indoors on a board. The iagram consists of three squares drawn inside ach other. In addition to the outlines of each quare, there are lines from the centre of each ide of the inmost square, through the centre of he sides of the middle square, to the centre of he sides of the outermost square. The corner f each square and the centre of each side are the 4 points of importance in the game. Each layer has nine men, often counters, and they lay in turn, placing a man at an unoccupied oint, and endeavouring to place three men in ne row, continuing, when all the men are placed, o try to form rows by moving men along the nes. The completion of a row entitles a player o remove, or "pound," one of his opponent's nen, the object of the game being either the apture of all the opposing men or blocking them o that they cannot move. The game has many ariations, and many names, including ninepenny norris; fivepenny morris, for a version played vith five men; and merils, marls, marrels, morals, norris and miracles, all for a version played with hree men.

Pall-Mall. Two London thoroughfares, Pall Mall and the Mall, are reminders that Pall-Mall was once popular. Often described as a fore-runner of Croquet, it was really more like a form of Golf, a game that arrived at about the same time, both having a common, if remote, ancestor in the Roman game, Paganica. In Paganica players walked across fields hitting a small, leather ball at trees with a curved stick, the object being to reach the target in the fewest possible strokes. It was played by country people, whereas pall-mall, which achieved rapid popularity in the seventeenth century, was a game for the nobility, though other people played simplified versions of it. Pall-Mall was played in special alleys, sometimes ½ mile long, and often surrounded by walls. A boxwood ball a foot in circumference had to be played down the alley, in which were a number of iron arches, in the fewest possible strokes. The player drove off as at golf, but, on reaching the arches, not only changed his club, but also substituted a small steel ball for the boxwood one.

Quoits. Dating back to the fifteenth century, quoits is one of those ancient games that had the distinction of being banned because its popularity as such that it was believed to be keeping people from archery practice. The ban was not effective, and it continues to this day, though it is now less played than it used to be, Scotland, the North of England, and Suffolk being, perhaps, the last main strongholds. The pitch consists of two circles or squares of clay, 18 yards apart, and each having in its centre an iron pin, called the "hub," 1 inch of which remains above the surface. The quoits are iron rings with a diameter that must not exceed 8½ inches. The weight is not fixed, but is often 3 lb. or more. The object of the game, which can be either singles" or "doubles," is to throw the quoit nearer or near the hub from the opposite point, 18 yards away, one point being scored for each quoit nearer the hub than the opponent's quoits, and two being awarded for a quoit that drops over the hub, called a "ringer." No points are awarded if opposing quoits are the same distance from the hub, and none are awarded if each side has a ringer. A game is 11 points in "singles," and 16 points in "doubles." Quoits developed from pitching actual horseshoes, and, to this day, some players make their first practice attempts at it with horseshoes. It is, in fact, to the large-scale disappearance of horses, and, therefore, of horse-shoes, from country life that some people attribute the drop in the popularity of quoits. It is interesting to note that, in the United States, horse-shoe pitching itself is a game, and one that is still popular.

Shove-Ha'penny. Shove-Ha'penny, an old English game that is still popular, uses a cushioned wood or slate board, divided by parallel lines across it into nine "beds." The "halfpennies" may be actual halfpennies, but are generally round metal discs. The object of the game is to shove the half-pennies into one of the nine beds, the shoving usually being done with the ball of the thumb, though any part of the hand may be used. First turn is decided by shoving halfpennies at the number nine bed, the best attempt winning. A turn consists of five halfpennies, and the winner is the first player to shove three halfpennies into each bed, halfpennies that touch the cushion not counting. Should a player place more than three half-pennies in any bed, his opponent can claim the excess, if he needs them, but cannot win the final point of a game in this way. Push-Penny, a similar game using three coins is played in some parts of the country, mainly in Lincolnshire.

Stoolball. Yet another ancestor of Cricket, Stoolball is still a popular girls' game. The wicket is a board a foot square on a pole 4 feet 8 inches high, the bat has a round striking surface, and the ball is rubber. Wickets are 16 yards apart and eight balls constitute an over.

Oxford and Cambridge Boat Race. *See* **Boat Races.**

Pall-Mall. *See* **Old English Games and Customs.**

Parachute Jumping.

Parachute jumping is generally regarded as a last-resort safety measure, to be undertaken only in a supreme emergency, and with considerable anxiety; but it is now also a recreation and a competitive sport, practised entirely voluntarily, and for enjoyment. This form of jumping may be said to have grown out of the Second World War, in which jumping was used to a far greater extent than ever before, and not only for escape in an emergency. Now, international competitions take place, and the sport has an enthusiastic following in Britain.

Parachute jumping as a sport involves jumps of particular kinds, including landings in a certain area, marked by a circle, and demonstrating turns and body control in the air, the parachutist regulating his direction by pulling down the lines of the parachute. Jumps of this kind may be made from about 6000 feet.

The first point that occurs to many people when they think about Parachute Jumping is that it is extremely dangerous. However, those who jump as a recreation maintain that this is not so, and that it is about as dangerous as skiing. Injuries are few and slight, and, in three years, none of the hundred-odd members of the British Parachute Club, of Fairoaks, Surrey, suffered anything worse than a sprained ankle. The parachutes used are so reliable that they still work even if they have been badly packed. A parachute consists of twenty-eight sections, called "gores," each divided into four panels, so that, even if a hole should stretch right across one gore, which is rare, the remainder of the parachute remains intact, and will bring the jumper down safely. As an additional precaution, jumpers wear a small reserve parachute on the chest, but this is hardly ever needed.

Training, which generally takes place at week-ends, starts with a period of learning how to fall, how to judge wind direction and speed, and how

to pack a parachute. The first actual jumps are from 2,000 or 2,500 feet. Both men and women take part in Parachute Jumping.

Parachutists must be licensed by the Civil Aviation Department of the Board of Trade, and they must produce medical certificates of fitness. Third party insurance is also compulsory, but this is automatically covered by membership of the British Parachute Association. Leading centres of Parachute Jumping are at Blackbushe Airfield, Hampshire; Thruxton, Wiltshire; Manchester; and Gleneagles.

Patience.

Patience is a card game for one person, and, though there are few different games for one, there are countless different forms of Patience. There are some using one pack, and others using two, almost all of them starting with the setting out of the cards on the table according to fixed rules, and having as their object the building up of the four suits on their aces.

The game that might almost be called the basic form of single-pack patience starts with a row of seven cards, only the left-hand one being exposed. Underneath this, and overlapping it, comes a row of six cards with the left-hand one exposed, and so on down to a " row " consisting of only a single exposed card, the exposed cards being left uncovered in each decreasing row. The object is to take out first the aces, and then the cards from two up to king, building each suit on its ace. From the " lay out," exposed cards can be moved when it is possible to put one on a card one pip higher in value of the opposite colour, when any card left uncovered by an exposed card can itself be exposed. The undealt cards can be played three at a time, the top one of each three being " playable," with the one underneath becoming " playable," if the top one is, in fact, played. The undealt cards can be played through three at a time in this manner as often as desired. A slight variation of this game allows the undealt cards to be played through one at a time, but this can be done only once.

Another single-pack game starts with a row of nine exposed cards, with, below it and overlapping, a row of eight, and so on down to one, all the cards being exposed, and the right-hand one being left uncovered in each decreasing row. The remaining seven cards form a separate row at the bottom. The object and the " move " are the same as in the previous game, only one card being moved at a time, and any card being eligible to fill any vacancy that might occur in the top row. Cards in the separate row can be played as required, but, once in the " lay out," they must remain there. This game is called King of the Belgians, and the last seven cards are referred to as the Belgian Reserve.

One to Six is a two-pack game. The player deals out a row of four cards, then discards two to a rubbish heap, and carries on like this until all the cards have been used. If, however, while doing it, he comes across any aces or kings, he takes them out, up to one of each from each suit, subsequently also taking out any that will fit on to these, building up from the aces and down from the kings. Then he goes through the rubbish heap, extracting any cards that will fit on the eight piles. The dealt-out cards, with the rubbish-heap cards, are then dealt again in the same way, the object being to complete the eight built-up suits in three rounds of dealing.

Polo.

Polo, one of the oldest of all games, originated in Persia, then spread in one form or another to China, Japan, and India, eventually being brought from India to England by cavalry officers in the second half of the nineteenth century. Later, it was enthusiastically taken up in the United States and Argentina. Played four-aside, and mounted, on a pitch that should measure 300 yards by 160 yards, its object is to score goals by hitting a 5-ounce ball through goals 24 feet wide with a stick consisting of a long cane fixed at a sl angle into a wooden or bambo striking head. game is divided into periods, called " chukk the number of periods varying slightly, as r be agreed for particular games.

Formerly, Polo was a game for the wealthy, it entailed owning and maintaining a string trained ponies. In recent years, however, cer stables and riding schools have provided facil for playing and practising Polo, and these facil include the hiring out of ponies. This appare simple and obvious step is actually quite a r lutionary innovation that has brought Polo wi the reach of almost anyone who wants to play, thereby increased the popularity of an ancient exciting game that might otherwise have died because of the expense involved.

Pony Trekking.

Pony Trekking as an organised recrea originated in Scotland in 1953, though someth similar was known in India before that. word *trekking* itself is Afrikaans. Chance coincidence played a part in starting Pony T king, at least on a larger scale than might ot wise have been the case. The first trek wa Newtonmore, Inverness-shire, and was pa organised by officials of the Scottish Counci Physical Recreation. At about the same time Aberfoyle, Perthshire, *Rob Roy* was being fil and many townspeople who came to watch pressed great interest in the horses. This led the planning of a trek in that area, the organi of which knew nothing of the Newtonmore ture, though they subsequently heard of it, received advice from its organisers. The trek from this second centre took place in 1 Now, there are about 70 approved centres, ma in Scotland, Wales, the West Country, and Lake District, though there are also some in land and on the Continent. " Approved," cidentally, means that they are inspected ev year by the Scottish Council of Physical Rec tion or the Ponies of Britain Club and hold Cer cates of Approval from one or other of th bodies.

Pony Trekking consists of riding over the h and moors, through forests and along anc tracks at a walking pace; for, if you ride fa than that, you cease to trek and begin to hack Riding). No experience whatever is needed, the complete novice or child who has never rid at all can enjoy Pony Trekking from the st During the first two days of a trekking holi beginners will be given some elementary inst tion in saddling, mounting, and starting and st ping the horse; and then they will start with sh treks of from five to ten miles.

There are two forms of Pony Trekking, trekking and post trekking. Most treks are treks, consisting of circular, all-day tours star and finishing at the centre. Post treks last several days, and include stopping at a diffe post or centre each night. There are comp tively few post treks, partly because they are suitable for experienced trekkers and partly cause of the difficulty of obtaining accommoda for one night only during the height of the holi season.

The Pony Trekking season is mainly from M until September, though some centres are o from March until December, and there is occasional one that is open all the year rou weather permitting. Details of approved cent including those especially suitable for child can be obtained from the Scottish Counci Physical Recreation, 4 Queensferry Str Edinburgh, 2, the Scottish Tourist Board Rutland Place, West End, Edinburgh, 1; or Ponies of Britain Club, Brookside Farm, As Berks.

Potholing.

Potholing might almost be described mountaineering in reverse, for it consists in exploration of underground passages, maybe depths of several hundred feet. Besides bein

hallenging recreation, it offers opportunities for pecialisation, *e.g.*, diving, photography, surveying, and can yield useful information in connection with water supplies, water pollution and hydroelectric schemes.

The main potholing centres in Great Britain are n Yorkshire, Derbyshire, the Mendips, and South Wales, regions where rainwater, carrying dissolved arbon dioxide from the air, has attacked the assive limestone rocks and the drainage has assed underground. The nature of the passages aries with the geological area. A system conaining many horizontal passages is known as a ' cave ", one with appreciable vertical drops as ", "pothole". Drops or "pitches" are comarable to waterfalls in a surface stream and often arry an active stream themselves. A pitch may e over 200 ft. deep, and the system may reach a otal depth of 600 ft. or extend for several miles. 'otholers make their descents by means of flexible adders constructed from steel wire and aluminium lloy. Recent developments include the adaptaion of skin-diving techniques and equipment to nable the more arduous passages to be explored.

The underground world is far more varied than ne would expect. The potholer's headlamp picks ut beautiful shapes formed by dripping water ontaining dissolved limestone—stalactites hang- ng like icicles, stalagmites growing from the cave oor, curtain-like forms hanging in petrified folds, nd smooth pebbles (known as cave pearls) in pure hite, orange, green, and black, according to the netallic impurities.

The beginner is strongly urged to join a club, hich organises trips and training and provides he proper equipment. Potholing could be angerous to the novice exploring alone, but as a lub member he (she) has the opportunity of aking part in an exciting and exhilarating sport, ne of the few left that gives the thrill of original xploration.

Public School Football.

All the forms of football popular to-day grew ut of the games played at various English Public chools a century and more ago. These games iffered widely, the rules often depending on urely local considerations imposed by the availble space. The Rugby game (*q.v.*) in its modern orm is, of course, still played, both at that school nd far beyond it; and other games that still urvive at the schools that originated them are he Eton Field Game, the Eton Wall Game, the Harrow Base Game, and Winchester College ootball.

Punting.

Punting consists of propelling a long, narrow, lat-bottomed boat with a pole, the punter standng up; and it can be either a pleasant, leisurely ecreation or a fairly strenuous competitive sport. The sporting side is governed by the Thames Punting Club, which has headquarters on the Thames at Staines in Middlesex. Women, as well s men, take part in competitive events.

Punting as a sport has the unique distinction of being confined, not only to one country, Britain, but to one river, the Thames; though in some parts of the world boats poled from a standing position are used for various purposes. There have been rumours that Japan has, or had, a similar sport, but these have never been authenticated.

Quoits. *See* Old English Games and Customs.

Race Walking. *See* Athletics, Walking.

Rackets.

Rackets is a fast, racket-and-ball game, played on a court measuring 62 feet by 31 feet, and using walls. A game consists of 15 points, unless 13-all is reached, when the non-server can set the game to 3 or 5, or 14-all is reached, when the non-server can set the game to 8, the game going to the first player to score the prescribed number of points. Only the server scores, the receiver taking over service when he makes a winning shot. When served, the ball must strike the front wall above a line called the "cut" line before striking any other part of the court, but, in play, it may be played either on the volley or after one bounce. If a player impedes his opponent, it is a "let," and the point is re-started.

Real Tennis.

Tennis, sometimes called "Real," "Royal," or "Court" Tennis, is a court game played with rackets and balls that has been called the King of Games, and that was once certainly the game of kings. Henry VIII played, and it is mentioned in Shakespeare's *Henry V*; but the first kings to play were of France, where the game originated.

It is a complicated game, and no description could give anyone who had never seen it an accurate idea of what it is like. Most racket-and-ball games use either a net, over which the ball is hit, or walls, against which it is hit, but Tennis uses both. Also, in most racket games, players change ends after so many games, but, in Tennis, they may do so during a game. Matches are in games and sets, a player winning six games completing a set towards the two out of three or three out of five that will make the match.

There are not many Tennis players in the country—there are only about a dozen courts—and very few women have ever played. People who do play, however, most of whom play other games as well, are almost unanimous in voting it the best of all games.

It is said that the term "love," used in so many games to indicate "nought," comes from Tennis, the original French term being "l'oeuf," which, in that language, actually means "egg"; an egg being, of course, something like the figure used for "nought." This derivation is not sufficiently well documented to be accepted as definite fact; but it is interesting to note that, in Cricket (*q.v.*), the term used for a score of "nought" is a "duck," or, in full, a "duck's egg."

Revolver Shooting. *See* Rifle Shooting.

Riding and Show-jumping.

The almost complete disappearance of the horse from everyday life has been followed by an increase of interest in Riding as a recreation. This is at least partly due to the great attention paid in recent years by both Press and television to one particular branch of horsemanship, Show-jumping. Before learning to jump, however, it is necessary to learn to ride, and many people never go, and have no wish to go, beyond the ordinary, unspectacular riding for pleasure that is called "hacking."

A great deal has been said and written about "correct" riding style, but, in actual fact, there are many different styles. The cavalryman, for instance, bends the leg to some extent; the Red Indian bends it to a much greater extent, more or less in the style that has been adopted by American jockeys; and the cowboy rides with an absolutely straight leg. Yet all these are expert horsemen. To assist in acquiring the normal English style, which is very close to that of the cavalryman, there is an old jingle that is now much less heard than it used to be, but is probably none the less helpful or accurate for that. It runs: "Your head and your heart keep up. Your hands and your heels keep down. Your knees keep close to your horse's sides, and your elbows close to your own." Old or not, anyone who learns it, and then builds up a certain amount of experience of putting it into actual practice is well on the way to becoming a rider.

Those who feel they would like to combine their Riding with something competitive might start with gymkhanas, which are sports meetings that generally include mounted equivalents of such novelty events as obstacle races and needle-threading races. For the more ambitious, gymkhanas could even be the first step towards the top-class competitive sport of Show-jumping.

Show-jumping. A Show-jumping contest is a mounted competition over a circuit of jumps, which the entrants attempt one at a time, each having the field to himself or herself, and being free to concentrate entirely on the jumps, without having to worry about other riders. The jumps, which have to be taken in a certain order, are of many kinds, including fences, double fences, walls, and water. Scoring is by points against, called "faults," so many being debited against an entrant for falling, knocking down an obstacle or displacing part of it, refusing, and other mistakes. Though the event is in no sense a race, there is normally a time limit that must not be exceeded, and, in some events, bonus points are awarded for fast rounds. Show-jumping is not restricted to riders who own their own horses, for some owners do not want to compete themselves, and are only too pleased to let good horsemen take their jumpers round for them. Incidentally, inexperienced riders taking up jumping for the first time will probably find it advisable to make some slight changes in their method of sitting in the saddle. Jumping needs a firm seat, and the novice rider may find it necessary to shorten the stirrups a little.

Allied to Show-jumping, and coupled with it in the difficult three-day competitions, is dressage. This is simply a mounted display revealing that the horse is obedient, balanced, supple, and, in a word, trained; and is a simplified form of the better-known "haute école," or highly-schooled riding. Good riders who seek absolute perfection can, if they are willing to pay for it, take an intensive course of haute école riding and all forms of horsemanship at the most famous of all riding schools, the Spanish Riding School in Vienna. Courses, which are conducted in German, consist of eight hours training a day for six months, and informality is not encouraged, the regulation dress for students being a bowler hat, black jacket, and white breeches. Riders who fall are immediately assisted by an attendant armed, not with a stretcher, but with a clothes brush. *See also* Pony Trekking.

Rifle Shooting.

Considered as a sport, Rifle Shooting, which might almost be called the modern equivalent of archery, had its origins in virtually the same conditions and circumstances that had popularised the older weapon five hundred years previously; though, unlike archery, it did not enjoy legislation aimed at abolishing other recreations in its favour. Both were encouraged because, in their respective periods, efficiency at them meant, not only success in competitions, but also the most effective defence in time of war, the great period of the rifle's encouragement for this reason being the latter half of the nineteenth century. Archery as a sport survives to the present day, and Rifle Shooting as a sport continues, though it can no longer be regarded as the most effective weapon.

With a normal rifle, with a calibre of about ·300 inch, competitive shooting is at ranges from 200 yards to 1000 yards, and there are many competitions, the greatest of them being the annual contest at Bisley, Surrey, for the Queen's Prize. Almost equally popular, however, is small-bore shooting, with a calibre of ·22 inch, and this, too, offers many annual competitions.

Revolver Shooting. Revolver shooting, often called pistol shooting, is also a competitive sport, and a very difficult one. Impressions gained from cinema and television screens might lead anyone who has never fired one to think that the revolver is an easy weapon to fire without fuss and with devastating effect. It is the very reverse of this. It is fired, not from the hip, but with the extended arm raised, which is how, in real life, it was generally fired in the old West. It is extremely difficult to hit even a man-size target at 10 yards, and very few people can call themselves good revolver shots, just as few of the old Westerners were good revolver shots. The difficulty is caused by the tremendous "kick" of a weapon that is held, not by both hands and pressed into the shoulder, as a rifle is, but by one hand. Revolvers have sights, but the nor method of aiming is by using the "instinc pointing sense," which is based on the fact t if you point at an object in the ordinary way, do, in fact, point accurately. This applies w pointing a revolver. As with rifles, small-b target shooting, in which sights are used popular.

Rink Hockey. *See* Skating.

Rock Climbing. *See* Mountaineering.

Roller Skating. *See* Skating.

Rowing.

Rowing, meaning simply taking a boat out the sea or a river for a short period, is a pleas recreation and a healthy exercise, but comp tive rowing is one of the most strenuous of sports.

A racing oarsman either rows, which means t he uses one oar, or sculls, which means two o Races are of various kinds, the best-known be for crews of eight oarsmen with a cox. T there are races for crews of four with cox, and crews of four without cox. There are also ev for pairs with cox, pairs without cox, double sc and single sculls. Eights, fours, and pairs r while double and single scullers, of course, s In fours and pairs without cox, and in all scull the oarsmen steer themselves.

Race Rowing is mainly a river sport, but t are races on the sea. For these, crews are usu fours with cox, and they use heavier boats t the normal racing "shell." (*See also* Boat Rac

Rugby Fives. *See* Fives.

Rugby Football.

As its name implies, Rugby Football is ba on the game played at Rugby School in the d when football was not organised and var schools played to their own rules. The stor how the Rugby game originated is well kn and widely accepted, but it is definitely not ac rate and possibly almost entirely apocryphal.

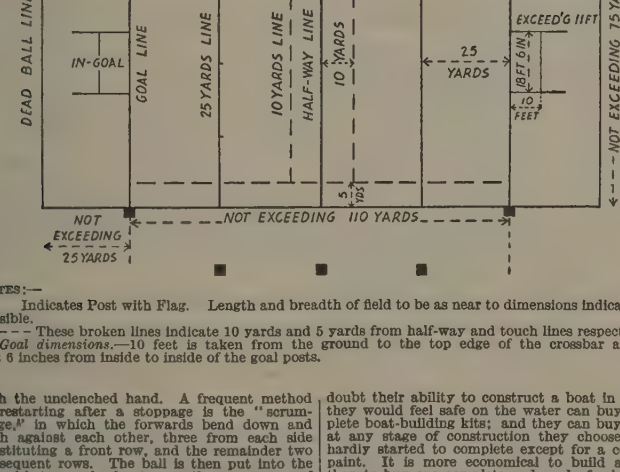
The story is that, in 1823, a boy named Will Webb Ellis disregarded the rules of that time handling the ball, and that handling was su quently made legal. In fact, handling the ball catching it was allowed at Rugby before 1 so, if Ellis was responsible for an innovatior was not by handling the ball, but by running w it after catching it. Running with the certainly became, and remains, the leading fea of Rugby Football; but the story that Ellis responsible, though commemorated by a pla at the school, was first heard years after El death, and he never knew of the fame that bec his. He was definitely at Rugby at the t though, and, a few years later, he played in first-ever Oxford and Cambridge cricket matc

The spread of the game beyond the school originated it has led to, not one, but two ga of Rugby Football, Rugby Union and Ru League. About twenty-five years after the g had become organised, with the Rugby U as its governing body, there was a dispute on question of legalising payment for time lost f work by players. The Union would not agre this, so twenty-two clubs, mainly in Yorksh seceded and formed the Northern Union, the Rugby League. Both bodies origin played the same game, but now, after over s years of independent existence, during wh each has made various rule changes, there some important differences.

Rugby was originally played twenty-as but it is now fifteen-aside in R.U. and thirt aside in R.L., the positions being seven backs eight forwards in R.U. and seven backs and forwards in R.L. Played on a pitch marked as in the diagram, and with an oval ball, Ru is mainly a handling game, the chief object b the grounding of the ball behind the oppone

pal-line. This is a "try," which counts three oints, and entitles the scoring side to an attempt o score a goal by kicking the ball over the cross-ar from a point measured in a straight line from here the ball was grounded. Other forms of oal are penalties, which may be awarded any-here, dropped goals during play, and goals om a "mark," after a player has signalled a fair catch" of the ball during play by shouting, Mark." In R.U. goals following tries, called conversions," count two, and other goals three. n R.L. any goal counts two, but goals from a mark" are not allowed.

The game is started, and restarted after a core. by a kick-off from the centre; and, there-fter, the ball may be advanced by kicking or arrying. It may also be passed from hand, but ot forward. Ball carriers may be tackled and rown down, and they may "hand off" tacklers though there is a top layer of clubs using part-time professionals.



OTES:—
Indicates Post with Flag. Length and breadth of field to be as near to dimensions indicated as ossible.
– – – These broken lines indicate 10 yards and 5 yards from half-way and touch lines respectively.
Goal dimensions.—10 feet is taken from the ground to the top edge of the crossbar and 18 et 6 inches from inside to inside of the goal posts.

ith the unclenched hand. A frequent method restarting after a stoppage is the "scrum-age," in which the forwards bend down and ash against each other, three from each side onstituting a front row, and the remainder two bsequent rows. The ball is then put into the nnel between the front rows, the centre man of ch, the "hooker," endeavouring to gain posses-on by hooking it back into, and generally right rough, his "scrum." In R.L. this method of starting is used whenever the ball goes out over e touch-line; but in R.U. the ball is thrown in raight along a "line out" of both sets of rwards, unless the side whose throw it is demand scrummage. In R.L. kicking the ball straight t over the touch-line is allowed only from a ee-kick, the penalty being a scrummage at the oint from which the ball was kicked. The effect the differences between the two games is at R.L. is faster and more open, and the ball more continuously in play. A game lasts for ghty minutes, divided into two halves.

In addition to Britain, both forms of Rugby e played in France, New Zealand, and Australia, d R.U. is played in South Africa. Both codes so have other, smaller "outposts" in various uropean countries, and there are minor R.U. ntres in North and South America. R.U. is ntirely an amateur game, and R.L. primarily so.

Sailing.

Mention of Sailing tends, perhaps, to conjure up visions of large, graceful yachts, beautiful to see, but clearly to be owned only by the wealthy. Sailing to-day, though, is very different from that. It is mainly sailing in small boats, many of them wholly or partly built by their owners. At first glance the building of a boat might seem a tremendous and highly skilled task, but, in actual fact, it can be as big and as hard or as small and as easy as the builder wishes. Some amateur builders start from the very beginning, acquiring the various materials needed bit by bit, and gradually bringing their boats into being. However, those who either lack the time for this or doubt their ability to construct a boat in which they would feel safe on the water can buy complete boat-building kits; and they can buy them at any stage of construction they choose from hardly started to complete except for a coat of paint. It is more economical to build a boat than to buy one complete and ready for launching, and the earlier the stage of construction at which the owner takes over, the greater the saving. Some owners claim that they enjoy the building as much as the sailing, and it is probably true that the owner who has done some work on his boat, however little, takes more interest and pride in the finished article.

The fact that boat-building is now within the reach of practically everyone means, of course, that the end to which it is a means, Sailing, is also within the reach of practically everyone, for few people are far from some suitable stretch of water. Where there is sailing, there are clubs, which the boat owner can join for quite reasonable fees, and which provide either sheltered moorings or "dinghy parks" where the boat can be kept.

Eventually, the small-boat owner may want to try racing his craft, and there are many events for boats of all classes and sizes. Racing is an enthralling pastime, for, though races are, of course, tests of speed, they are also very much more than

that. There is tremendous scope for tactics, and the sport is in every sense a highly skilled one, as well, incidentally, as one with an interesting history behind it.

Skating.

At first glance, ice-skating would not appear to be a normal activity for British people, for it is a part of Winter Sports (*q.v.*), which are possible in Britain only rarely and to a very small extent, and it was formerly restricted to brief periods when rivers, lakes, and ponds were frozen. Despite this, however, the people of this country have always appeared to possess a natural talent for it, and they have practised it whenever opportunity offered. The history of British Skating goes back a very long way, and includes occasions when Skating was possible, and took place, on the Thames, as well as many, more regular instances in the Fen district and other places. In recent years this wish to skate on ice has been catered for by the opening of many indoor rinks, which make the skater independent of weather and daylight, and enable Skating to be carried on throughout the year.

Many people ice-skate just for recreation, health, and amusement, but anyone keen to carry Skating a stage farther and acquire a higher level of skill can find a wide range of opportunities from which to choose. Figure-skating is very popular, and for those anxious to test their skill at it there is a series of medal tests, in which the skater is not in competition with anybody, but is attempting only to reach a fixed standard. Beyond these, there are many competitions and championships. Dancing on skates also attracts many people; and also offers those interested standard medal tests and competitions.

Another popular skating activity is speed-skating, which takes place indoors and, whenever possible, outdoors as well, though the methods and techniques of the two forms of racing differ widely. Outdoors, the skaters normally race in pairs, though each man is timed, and is actually racing against the whole field. Much of the racing is on long, straight stretches of ice. Indoors, skaters race perhaps four at a time, and are directly opposed to those on the ice with them. These races are on small tracks, a lap sometimes being no more than 130 yards. Standard outdoor distances range from 500 to 10,000 metres, while indoor races go from 440 yards to 2 miles. There are also indoor relays, generally of 3 miles, in which teams of four race on the "Madison" method, relieving each other, not at fixed points, but at will. In addition to competitions and championships, speed-skaters also have their standard medal tests.

Ice, however, is not the only surface on which Skating takes place for, following an unusual history, roller-skating also maintains a large following. Roller-skating was originally introduced long before the arrival of the indoor ice rinks purely to provide ice-skaters with some kind of substitute when no natural ice was available. It progressed by fits and starts, varying from extraordinary "crazes" when it seemed that everybody was roller-skating, to periods when nobody appeared to be doing so. Eventually, it settled down to a steady existence as a popular recreation in its own right that has in no sense been pushed into the background by the increased facilities for ice-skating. The opportunities it offers are almost identical with those of ice-skating, for they include figure-skating, dancing, and speed-skating, with championships, competitions, and standard medal tests in all branches.

Both forms of Skating also offer a team game, and in both it is hockey. Ice-hockey, which is called simply hockey in Canada, where it or nated, and the United States, is played six-as with substitutes permitted, and with a rub disc, called a "puck," instead of a ball. first began to win popularity in Britain soon a the First World War, and since then has had rat a chequered career, helped forward by the se professional players from Canada, who play the National League teams, and held back by lack of facilities for British youngsters to pract for practice sessions mean closing rinks to all other forms of Skating for certain periods. game should, however, survive, for there i definite demand for it.

Roller-hockey, generally known as rink-hock bears a closer resemblance to its parent ga outdoor field hockey, than does ice-hockey. is played with a ball, and is five-aside, with substitute permitted. Its popularity is such t it is now played throughout the year.

There is a form of hockey on ice that clo resembles outdoor hockey. This is Ban which originated in England, but is no lon played here, though it is popular in Sweden the U.S.S.R. Some other games have been t on skates from time to time. One is Badmint which has been played on ice, but only a stage exhibition. Basketball on roller-skates been tried in several countries, and might develop and spread.

Skating is not so much a recreation, sport game as a whole series of different recreati sports, and games. Each has its following, a while there are enthusiasts who are interested both ice- and roller-skating, or in more than branch of one or both of them, there are m ice-skaters who have no interest in or knowle of roller-skating, and vice versa, and many k supporters of just one branch of Skating hardly know that the many other branches e It is, of course, quite possible to take part in b ice- and roller-skating, and in more than branch of Skating, and greatly to increase o enjoyment by doing so.

It is not particularly hard to learn to sk It requires strong ankles, a good sense of bala and plenty of confidence; and it is possibl start practising, at least to a limited extent home, for instance, by getting used to stand on skates. Skating is probably more ea mastered when young, but many adults h successfully taken it up.

Skittles.

Skittles has been played in England since 13th century and came from Germany wher was known as *Kegel*. There are several versi but all consist in throwing a ball down a l alley at a set of pins.

In English Skittles, the ball is a flat-sided ob called a *cheese*; in German and Dutch Skitt round ball is used. Both types of ball weigh least 10 lb. and sometimes as much as 16 Over the years the number of pins has va between 3 and 17, but the normal number hence the alternative name of Ninepins, thoug some parts of England 10 are still preferred.

English Skittles, using nine pins, is played i alley about 12 yards long and 3 or 4 yards w The pins are set up in diamond formation, players throw the cheese at them from a dista of 6 or 8 yards, being allowed one step forw during the throw. There are several method scoring. In one, the object is to score 31 i few throws as possible, each pin knocked d counting 1, and any throw in which more than number still required are knocked down counting. Another method is to knock down many pins as possible in a fixed number of thr

e highest total winning. Yet another allows ch player three throws in each of a fixed number turns, scoring being 3 if all nine pins are knocked wn in one throw, 2 if in two throws, 1 if in three rows, and 0 if any are still standing after the three rows. Pins must be hit by the cheese direct or another falling pin. Pins knocked down by bounds do not count.

The Dutch introduced Skittles, as played with a und ball and nine pins, to America in the 18th ntury. The game rapidly became popular but 1841 it was made illegal because of the betting t it. However, the law specifically mentioned nine pins", so the organisers simply added a nth, and the game survived. As Bowling, it came very popular in 1952 when a machine was vented for replacing the pins automatically and ere are now over 30 million players in the United tates.

In 1960 this form of the game reached Britain here it soon became easily the most popular rsion of Skittles, there now being well over half million players. There is a British Tenpin owling Association and a Tenpin Bowling Proietors' Association of Great Britain. The bowls," some of them converted cinemas, offer any of the facilities of a social club. Competent structors are available at them, and there are ountless competitions and leagues.

ooker. *See* Billiards.

owshoe Running. *See* Winter Sports.

ftball. *See* Baseball.

lo Whist.

Solo Whist is a card game for four players, who rmally act independently. Play is as at Whist (*q.v.*), but the cards are dealt in threes, the final und being dealt singly, and the dealer exposing s last card to indicate trumps.

Players then "declare" in turn, starting with e player on the dealer's left. The lowest call is l propose," which entails making eight tricks ith a partner, any one of the other players being igible to "accept" in his turn. The next call is Solo," which requires five tricks to be made assisted. Next comes "Misère," in which ery trick must be lost, and then comes "Abonance," in which nine tricks must be made. igher still is "Misère Ouverte," in which every ick must be lost with the player's hand exposed. d highest of all is "Abondance Declarée," in hich every trick must be made. Any player ay "Pass," and, once a call has been made, ter callers must make a higher call or pass.

Though calls are made with trumps already minated, certain calls may alter the trumps; d, with regard to these, there are several views, quite widely held, as to the rules that should pply. A player calling Abondance can choose s own trumps, though Abondance in the minated trumps—called Royal Abondance—kes precedence over the same call in another it. In Abondance one school of thought holds at the first round is played on the nominated umps, while another takes the view that the st card only is played on the nominated trumps. either of these circumstances a player making is call should not announce his trumps until the und or card has been played, unless it is necesry to announce Royal Abondance to overcall. ere is, however, a third view, and it is the view the majority of authorities who have actually ritten about the game, that the new trumps ould be announced before the hand starts. so the subject of differing views is Abondance eclarée, one view being that the caller can oose his own trumps, and another that, in this l, there are no trumps, though both views agree at this call confers the right to lead. A good ayer can easily adapt himself to any of these riations, the important thing being to check hich versions are being used before starting to ay. On the Misère calls there are no trumps, and in Misère Ouverte the player need not expose his hand until the first round has been played.

Speed-Skating. *See* Skating.

Squash Rackets.

This game is played on the same principle as its forerunner Rackets (*q.v.*) but in a smaller court, with a shorter racket and a rubber ball. It is mainly a singles game, though doubles can be played.

The court has four walls with the rear part divided into two service courts, each having a small "service box" down the court by the side wall. The server must have one foot in the box and serve the ball on to the front wall above the "cut" line (6 ft. in singles) so that it comes back diagonally into the other service court. But it need not land direct, or land at all, but may strike the side wall or back wall or both and be volleyed by the receiver. The object of the game is to score points by striking the ball in such a way that the opponent is unable to return it or make a proper shot. Every shot played in a rally must hit the front wall (directly or via another wall) and must be played on the volley or after one bounce. The service ball must always hit the front wall first. Service proceeds from the two boxes alternately. It is important to note that unlike Lawn Tennis (*q.v.*) services that would be faults become good if taken by the receiver. A game is 9 points but if 8–8 is reached the winner is the next to score 2 consecutive points. Only the server scores points, winning shots by the receiver entitling him to take over the service. Players sometimes accidentally impede each other and when this happens it is a "let," and the point is replayed.

The game enjoys great and increasing popularity. The Central Council of Physical Recreation co-operates with the Squash Rackets Association (the game's governing body) in running courses and there are coaches at many clubs. Though many people play purely for exercise and enjoyment, there are many competitive events, both national and international. Internationally, Squash Rackets is largely dominated by the Egyptians and Pakistanis but a rapid rise in popularity, comparable with that in Britain, has brought Australia very close to the top. The game has developed along slightly different lines in the United States, but with the growth of international competition and the formation of an International Federation the differences from the standard game are likely to disappear.

Surf Riding. *See* Swimming.

Swimming.

Swimming is an extremely popular pastime that also shares with walking the distinction of being a perfect exercise for health, as it exercises the whole body, and can be carried out as easily or as strenuously as the swimmer wishes. It is also a very useful accomplishment that may at any time put its possessor in a position to save a life.

There are several different swimming strokes, the basic stroke being the breast-stroke, now often seen in an alternative method, the butterfly. Faster strokes include the side-arm, the overarm, the trudgeon, and the crawl, but each of these attempts to speed up progress through the water has really superseded its predecessor, and the crawl is now almost universal. There are also two strokes used in swimming on the back, one being a back equivalent of the breast-stroke, and the other a back crawl. It is possible to swim under the water, using the breast-stroke, and to keep the eyes open while doing so. It is also possible to swim down through the water to retrieve objects that may have been dropped.

Ascending through the water is automatic, though it can be hastened by a kick. Remaining stationary in deep water can be achieved either by floating on the back or by treading water, which simply means moving the legs gently up and down.

It is not difficult to teach oneself to swim, and, like cycling, it is an accomplishment which, once learned, is never forgotten. The main thing is confidence, or an absence of any fear of the water. Such fears are quite unnecessary, for water is an element that always tends to keep a human being on the surface, and not to draw him under. Going underneath the water, and staying underneath, requires a definite physical effort, and, if that effort ceases, the swimmer is automatically brought to the surface again. Many non-swimmers who get into difficulties increase these by struggling wildly, for, by doing so, they may easily take and keep themselves under. If they would make only the gentle movements of treading water, they would both stay afloat much longer and present far fewer problems to any swimmer who might be trying to save them.

Saving life in the water is the object of the Royal Life-Saving Society, which teaches the best methods of bringing people who are in difficulties ashore, and also methods of artificial respiration for use in reviving the apparently drowned. Every swimmer should acquire some knowledge of life-saving, for even a strong swimmer may experience considerable difficulty in saving anyone unless he or she has some idea of the best way of setting about it. Many swimmers, for instance, normally use only the crawl and the back crawl, whereas, to save anyone, it is almost essential to use either the breast-stroke or its back equivalent.

Swimming has a well-organised competitive side, with many competitions and championships right up to the Olympic Games. Most races take place in baths, but there are some river and sea events, and the greatest competitive challenge to any swimmer is, of course, the English Channel. Although this has been conquered many times, the swimming of it remains, and will always remain, a wonderful achievement.

Diving. Generally accepted as being akin to Swimming, though actually it is quite a different sport, is Diving. Competition Diving means using boards of various heights, performing certain set dives, and choosing additional ones from an approved list. Diving requires a certain amount of nerve, and also gymnastic ability, including the ability to control the body in the air. Whereas strong swimmers are generally fairly big, divers are often much smaller and more compactly built.

Water Polo. In view of the popularity of Swimming, it is not surprising that there is a water team game, this being Water Polo, in which the object is the scoring of goals, the ball and the goals resembling those used in Soccer, though all shots and passes are, of course, thrown. Throughout a history of nearly eighty years, Water Polo has been beset by rule trouble, and has probably been the subject of more codes of rules than almost any other game. The difficulty is the detection of fouls under the water; the ideal, a game of the basketball type, free of bodily contact.

Surf Riding. Though straightforward Swimming, Diving, and Water Polo are the chief competitive water sports, there are other water activities with large and, in some cases, growing followings, some of them also having their competitive side. Fairly old-established is the Hawaiian sport of Surf Riding, which has been seen though generally in a rather milder form, in many parts of the world. It consists of placing a flat board on the water, and then lying, or, more rarely, kneeling or standing on it, and being carried ashore on the crest of a wave.

Underwater Swimming. Undoubtedly the fastest growing of all swimming activities is Underwater Swimming, which is a link between ordinary diving and swimming under water, the swimmer, depending on his own lungs, to remain below for only a few seconds, and t fledged deep-sea diving, with the diver we down with equipment and receiving assis from the surface. The underwater swi receives no surface assistance, but he doe light equipment, consisting of an artificial " l and breathing tubes, and also a mask and fi This type of swimming developed during Second World War, in which Naval under swimmers, called "frogmen," rendered services. Frogmen can also render useful se in peacetime, in, for instance, the some necessary searching of rivers and canals underwater photography; and in expl wrecks, and even old, lost cities, now u water. There is also a vast amount of k ledge, excitement, and pleasure to be gained a "close-up" study of the many fascinating as of the underwater world.

It might be thought that the first step to becoming an underwater expert was to be an expert swimmer, but it is not essential f underwater swimmer to be a surface swimm anything like championship class. There a course, dangers, and the newcomer to Under Swimming should not go down too deep un has had a good deal of practice and gain certain amount of experience. Preferably first descents to any depth should not be u taken alone, and if the swimmer has gone deep he should come up slowly, otherwise he getting the "bends," which is caisson di and means that reduced air pressure has c nitrogen bubbles to form in the tissues. may also be danger from large fish, and u water swimmers should not venture into unc caverns without a light. It is always adv to collect as much local information as po before diving in a strange area. Though all of equipment, including cameras, harp knives, and torches, can be carried, the beg will make a better start if he dives withou cumbrances. Most of the dangers can be av or circumvented with care, and the rewar those who master Underwater Swimming whole new world to explore.

Table Tennis.

Originally simply an amusing parlour known as "Ping-Pong," Table Tennis is n serious, world-wide, competitive sport, with championships and tournaments, and the a to attract crowds of 10,000 spectators.

Resembling a miniature game of Lawn T (*q.v.*), the net is set on a table 9 feet long by wide, and the ball is a very light celluloid Players serve series of five balls in turn, server and receiver scoring. The service h bounce first on the server's side of the net then on the other, and, thereafter, all strok "ground" strokes, volleying not being all A game is 21 points, and matches are usual best two out of three or three out of five g "Vantage" games are played, as, if the reaches 20-all, each player serves once in turn one has a clear lead of two points. Both s and doubles are played.

Table Tennis requires perfect fitness and second reactions. Many Lawn Tennis p also play Table Tennis, and several of these found it desirable to retire from the fast game before giving up the outdoor game.

Tennis. *See* Lawn Tennis, Real Tennis.

Tobogganing. *See* Winter Sports.

Traditional Games and Customs.

Traditional and unusual sporting event plentiful in many parts of the world, but few a longer tradition behind them than the Ca Livrea that can still be seen, over 500 years its inception, in the Italian city of Florenc

a version of Football, based on an ancient eek game called Episkuros and the old Roman ne of Harpastum. Played twenty-seven-aside a pitch rather smaller than an Association tball pitch, it was originally restricted to the bility, and in 1672 a game was cancelled when was discovered that the selected teams included yers who were only "gentlemen." The linary people did play, but the game as played them was called Calcio Divisi, and was not garded as the same thing. The playing of lcio in Livrea faded out in 1739, but was re-ved in 1898, to stop again in 1902, only to be rived once more in 1930. To-day, there are nerally two games a year between teams no ager restricted to the nobility and representing e four quarters of Florence. They are wonder-spectacles, for the players, and also numerous ficials and attendants, wear fourteenth-century stume, and the games are preceded by cere-onial processions, and by a special address to e most distinguished person present. The ophy for the games is traditionally a white calf.

Another ancient Italian sporting event that still rvives is found in Siena, and consists of horse-cing in the city. It is a wild and fierce form of cing in which virtually anything that might rther the cause of victory goes on between the lers. Riding events, many of them of great tiquity, figure prominently in countries in hich great horsemanship is an age-old tradition. ssia offers Kop-Karri, a fifteen-aside mounted me that is a battle for possession of a sheep's lt. Riders carry their reins in their teeth to ave their hands free for the fight, and anyone ho gets the pelt is soon downed in what is one of the roughest and toughest games of all time. ayed now by Kazakhs from the Steppes and ddilka from the Afghanistan border, this game riginated in China, and was brought out of that untry by the riders of the Golden Hordes of enghis Khan. Also found in Russia is the ounted Kissing Game, in which a galloping male rseman seeks to snatch a kiss from a girl rider med with a whip.

Horses are also prominent in North American odeos, which consist of competitions in cowboy ills, such as riding, roping, steer-wrestling, and uck-wagon racing, which can still be seen nually in rodeos like the famous Stampede at lgary in Alberta. Rather different are Chilean odeos, which consist mainly of displays in-olving horses and young bulls, and the Tope-lura, in which two mounted teams push against long log suspended horizontally between them. hilean Rodeos carefully avoid anything that ight harm the animals, which enter into things ith excitement and enjoyment. This also pplies to the bull races at Pamekasan in the onnese island of Madura. Based on the local ethod of ploughing, these consist of races in hich a driver stands barefooted on a small ooden sled harnessed to a pair of bulls, though ese need little driving. In India, elephant cing may be as much as a thousand years old, t it is now being allowed to decline because of puted "feudal" associations. Recently, there as a not-very-serious attempt to introduce it to the United States, which is, however, more home with events like Florida's Swamp Buggy erby, in which vehicles carrying two hunters and eir equipment must cover a figure-eight course 'a mile within ten minutes.

Differing widely from these events in every-ing but speed is Pelota, or Jai Alai. Played in pain, France, Portugal, North Africa, and South nd Central America, pelota is a traditional asque game that developed from a medieval rm of handball that was played against village urch walls. To this day, many pelota courts, alled "canchas," are next to churches, the wall, r "fronton," which is an integral part of the ame being that of the church, and the priest ery often being one of the best of the local layers. The game, which is very fast and ex-austing, can be between two players or between eams of two or three, and consists of playing a all that is rather smaller than a tennis ball gainst a wall with either the hand or, in the case f the most popular form of the game, the Grand histers, with a long, narrow, wicker basket, called a "chistera," that is strapped to the player's hand and arm.

Personal combat sports have always been popular, and Switzerland has a national sport of this type that had its first big tournament in 1905 in Das Schwingen, which means "The Swinging." It is a form of wrestling, in which the contestants, normally very powerful Alpine herdsmen, wear special belts and shorts by which holds are taken. The traditional prize for the winner of the annual Swiss championship is a two-year-old heifer. Iceland has a rather similar form of wrestling, called Glima. Much less similar is the Siamese form of boxing. Competitors in this wear, and use, ordinary boxing gloves, but they are also allowed to use their elbows, knees, and feet, which are bare.

Next, a group of recreations in which the feet are used less lethally, starting with the Netherlands, and the Nijmegen Marches. Over half a century old, these are international long-distance walks that are not races, but reliability trials, in which complete teams must start and finish together within a certain time. The marches take four days, the distance to be covered each day varying between 25 and 30 miles according to the class. Classes catered for include men, women, and also police teams, walking in uniform, and military teams, carrying equipment. The walks, which attract over 10,000 competitors every July, are an unusual and colourful spectacle, and the opening ceremony is as well worth watching as that of the Olympic Games. British walkers, civilian, police, and military, regularly take part. Though called marches, they are really walks; and it is unlikely that many men would consider real precision marching as a recreation. However, women do in at least one country. This is New Zealand, where marching competitions are held between teams of twelve, with a leader, each team wearing a special uniform, and carrying out a three-minute routine to the music of a pipe band. Points are awarded, not only for the marching, but also for the costumes and the leading. Though the competitions are confined to women, teams are generally trained and drilled by men. This type of marching was seen in Britain a few years ago, when the Blair Atholl team toured the country giving demonstrations.

About fifty years old in its own country, Sweden, and quite likely to spread to other countries in the future is Orienteering, which consists of finding one's way about the country from one control point to another by using maps and compasses. Generally carried out on foot, and in wild country, it can also be done on horses, bicycles, motor-cycles, skis, and skates, and in cars and canoes, and in any kind of country, including urban areas. During the Second World War, in which Sweden, though not involved, had to be ready, Orienteering was extensively used in military and civil defence training; and it was then that night Orienteering began, with competitors wearing lamps strapped to their foreheads. Probably the most strenuous annual event in Orienteering is the Swedish three-day mountain race, in which contestants, working in teams of two, have to cover 60 miles of mountains, forests, and swamps on foot, carrying equipment that must include tents and food. Though mainly confined to Sweden, Orienteering has been successfully tried in Canada and the United States, where it acquired its English-language name.

Non-English recreations that English people do not have to travel very far to see are the many and various activities that go to make up Scotland's Highland Games. Highland Games meetings, or gatherings, are sports meetings, but sports meetings with their own definite and extremely colourful and spectacular characteristics. The chief sporting events at them are the "heavy-weight" events, including tossing the caber, throwing the hammer in the Scots style, putting and throwing weights of various sizes, and wrestling. In addition, there are competitions in Highland dancing and piping, and often for pipe bands, all playing their parts in a spectacle that can hold its own with any of the many spectacular events that love of tradition and love of sport have combined to produce all over the world. (*See also* Old English Games and Customs.)

Trampoline. *See* Gymnastics.

Tug-of-War.

A Tug-of-War is one of the least complicated and one of the most strenuous events in sport. It consists of eight men pulling on a rope against another set of eight pulling in the opposite direction, each team trying to pull the other forward across a line, and each helped by a coach, who instructs them when to " heave " and when to concentrate on resisting the opponents' heaves. A pull may be over in a few seconds, or it may take many minutes. Contests are generally the best two out of three pulls, and a competition may involve three such contests in one afternoon. Competitions may be at " catchweights," which means that there is no weight limit, or they may restrict the eight men to a total weight of, say, 104 stone or 100 stone. The Tug-of-War requires, and will help to develop, great strength.

A popular event that always arouses great enthusiasm amongst the spectators, the Tug-of-War fully merits this position, but it owes some of its success to the fact that it was introduced into the right place at the right time. In the nineteenth century, before athletic sports were really organised, most country sports meetings included events like obstacle races, sack races, and egg-and-spoon races. These, however, though they are found to this day in some children's and local sports, grew less popular, and began to give place to more " serious " ones, favourite replacement for them being the Tug-of-War. Then athletic sports became organised, and the Amateur Athletic Association was founded, and instituted its famous annual championships, including two Tug-of-War championships that still exist, where, a few years earlier, there might have been obstacle-race and sack-race championships.

For years, service units and police forces provided the leading Tug-of-War teams, but, more recently, they have been challenged by teams from big firms. A still later development has been the formation of clubs concentrating entirely on the Tug-of-War. Organisations and clubs with Tug-of-War teams now have their own association, and their own annual championship meeting.

Underwater Swimming. *See* Swimming.

Underwater Watching.

In recent years there has been a considerable increase of interest in the undersea world; and some participation in this has been brought within the reach of those who are unwilling or unable to take part in underwater swimming and diving by the use of glass-bottomed boats, often boats in which the viewer slides back a wooden panel at his feet to reveal the glass viewing panel. Such boats, of course, can only be of use where the water is exceptionally clear and transparent, but, where conditions are suitable, a surprising amount of the life and colour of the world beneath the seas can be seen, and without any of the strain or danger of diving.

Much of the Mediterranean Sea fulfils the necessary conditions of clarity and transparency, particularly, perhaps, the coasts of Corsica, Sardinia, Sicily, and Italy itself. Greek and Egyptian waters are also clear, as are the waters of the Spanish Costa Brava and the Balearic Islands. Going farther afield, there are very transparent waters off parts of the Australian coast, and, of course, in the West Indies.

Volleyball.

Long-established in the United States, and played also in some other countries, Volleyball is a comparatively recent arrival in Britain, where it has been encouraged by leading personalities from the sport of Athletics, who saw in it an ideal game for maintaining fitness, and formed a governing body to organise and control it. A league started in London owed much of its early success to players of nationalities other than British, but the game took a big step forw when it was adopted by the London Fire Bri as an effective method of physical training.

Volleyball might be compared with Basket (*q.v.*) in that it is a team game that can be pla indoors, though it can also be played on out courts. The actual game, however, differs wi from Basketball. Played six-aside on a r angular court that should not exceed 60 fee 30 feet, it consists of " volleying " an inflated across a net 8 feet high with the hands, the ob being to make it touch the ground in the oppone court, while preventing it doing so in your ow

Water Polo. *See* Swimming.

Water Skiing.

Water Skiing originated in the United State the early nineteen-twenties and actually desc from Surf Riding (*q.v.*). Surf Riding le Aquaplaning, in which a board was towed b motor-boat with the rider standing. A fur development saw the board giving place to ac skis and Water Skiing was born. It eventu reached France, and then, in 1950, Britain.

In Britain, it rapidly became popular, pa through television, which demonstrated it wh was still in its infancy. This led directly to sev new Water Skiing centres being opened u various parts of the country. Britain now over 75,000 water skiers and there are abo hundred clubs, most of them affiliated to British Water Ski Federation. The Federat which is second in size only to that of the Un States, is in turn affiliated to the World W Ski Union.

Water Skiing has been described as the f family recreation, for, though, at the highest l it requires great skill and daring, almost any including children, can quite easily acq sufficient skill to enjoy it as a recreation. more ambitious can, if they wish, proceed to variations as monoskiing, using only one slalom, when the skier, generally on one sk towed through a staggered arrangement of bu jumping, from a ramp between three and six high; and tricks, which vary from the quite sim to the very difficult. There are Water Sk championships, both national and internatio these involve slalom, jumping, and tricks.

The Central Council of Physical Recrea holds Water Skiing courses and there are coaches at many clubs. Water Skiing can practised in a swimming suit, but many sk wear special rubber suits, or at least jackets.

Walking.

Walking comes so naturally that few pe ever think about it. It is, however, w thinking about, for it is the basis not only everyday life, but also of every physical opposed to purely mental, recreation, sport, game, all of which involve, if not actual walk then running, which is an equally natural beyond walking. It is also the basis of train either for health and fitness or for a strenu sport. It has been said that it is impossibl walk too much; and, while those who have d little walking would, of course, have to incr the distance gradually, there is no doubt th regular, daily two- or three-mile walk woul itself prove an effective method of maintai health and fitness.

A great deal of pleasure can be added to wal about the countryside by taking an interes those things which will help you to understand history of this island. The countryside is ric churches, historic buildings, ruins, wayside cro prehistoric camps, and dykes. Besides a g pair of shoes you need a pencil, a notebo 1-in. Ordnance Survey map, a good guide b and a fund of optimism, imagination, and curio During your rest intervals you can study the m and plan, and read one or more of the many b ground books to supplement what you have n and stimulate you to further adventure. only is our countryside full of interest, it is markably varied. Among the organisations wh

vide rambling opportunities are the Ramblers' ociation, the Holiday Fellowship, and the Co- rative Holidays Association. *See also* Long- ance Routes, Section L.

ght-lifting.

Veight-lifting is a method of exercising to ntain health and develop strength; a system raining that can usefully be at least a part of preparation for almost any sport or game; a highly organised and very popular com- tive sport in its own right. Once, quite neously, thought to be an over-strenuous and angerous" activity, it has now, in more en- tened days, seen the pendulum swing com- ely in the opposite direction, with professional amateur sportsmen of all kinds freely admit- how much they owe to it, and a large follow- of seekers after health and fitness, including nen, many of them actresses, models, and ers whose work demands a near-perfect re.

When it is used as exercise and training, the nuousness of it depends entirely on the wishes he lifter or his or her adviser; for training with ghts does not mean lifting as heavy a weight ossible, but carrying out a certain number of etitions in various styles with weights well hin the lifter's capacity. For those keen to elop the maximum strength of which, accord- to their build, they are capable, weight- ng is certainly the quickest, and perhaps the r, way of achieving this. One of the charges elled against it is that it makes one slow, but is just another fallacy. It does not; and npetitive weight-lifters actually make some of fastest movements known in sport.

s a competitive sport, Weight-lifting is ided into weight classes, and there are many rnational and national championships and npetitions. The sport is popular almost all r the world, and has been firmly established in tain for many years.

Strand-Pulling. Akin to Weight-lifting in that is a method of keeping fit and developing ngth that is also a competitive sport is and-pulling, using a steel or rubber expander. ious different "pulls" are possible, and the ngth and resistance of the expander can be ered at will. Many people use this old- ablished system of exercising for health and ngth; and, for those interested, there are ny strand-pulling championships and com- itions.

ist.

Whist might be called the standard card game. hns never excited quite the furore of Bridge), but it is long established and popular, both home and at Whist Drives. It is probably the t card game, apart, perhaps, from a few simple nes depending on luck, that most people learn. d it provides a sound foundation for the embryo d player.

t is played by four people, two partnerships two opposing each other, and with a normal k of cards. The partners sit opposite each er; and the pack is shuffled, cut for trumps, d dealt out singly. The cards are then played t in thirteen tricks of four each, the player on dealer's left having first lead, and the winner each trick leading in the next. Ace counts as highest card—except in cutting, when it nts as the lowest—and it is followed by king, een, knave, and then on from ten downwards. e higher card of any suit takes the lower, unless trumped by a player unable to follow suit, the cks being gathered up by the winner as made.

It is necessary to concentrate, to watch the ds played, and to endeavour to "place" the played cards. This comes with experience, as es an understanding of such unwritten rules as Second in hand plays low" and "Third in han ys high," and a knowledge of when to dis- ard these.

Three-handed Whist is possible, one suit being discarded.

Winter Sports.

There are few fields of recreational or sporting activity to which, given the opportunity, British people take more eagerly than Winter Sports. Enthusiasts from Britain were going abroad to find, and in some cases start, them before the turn of the century; and to-day there are probably a hundred travellers for every one who went sixty years ago.

Switzerland is, of course, the traditional objective, but there is actually a wide choice, for facilities exist in Norway, Austria, Italy, France, Germany, and Czechoslovakia. There are opportunities to suit most purses, and to suit both those who want only sport and those who want sport combined with entertainment. If the object is simply Skiing, the most popular of the winter sports, there is really no need to travel further than Scotland, which provides excellent facilities, and is increasing these every year.

For those whose time and experience are both limited, skiing is normally of the downhill variety, rather than the lengthy journeys on the level as well as on hills, and up as well as down, at which many Continental, and particularly Scandinavian, skiers are adept. Greatly increased facilities in the way of ski-lifts enable the holiday skier to work in three times as many descents as the skier of only a few years ago. Almost every resort has a ski-school with an English-speaking instructor, and it is always advisable for a novice to join this. It is also advisable for novices to start training for a ski holiday some time in advance, both by ordinary physical training and by attending a dry ski-school. The air in winter sports resorts encourages more activity than is good for a completely untrained person, and the fitter the skier, the less his chance of being injured. Skiing accidents are plentiful, but many of them could be avoided by the exercise of a few simple precautions. Having lessons is one; being fit is another; short skis with safety bindings are still another; and refusing to ski late, which may be any time after four o'clock, is yet another, for, as the light fades, it is replaced by a bluish light that makes uneven patches difficult to see, and the snow tends to ice over. Most winter sports equipment can be hired, but hired or bought, and regardless of the extent to which fashionable skiing clothing may be advertised, the most important items are the boots. The winter sports season lasts from December until March, but the snow is sometimes late, and, while Christmas and New Year should be safe enough, February offers the certainty of snow, combined with longer days.

Ski-jumping is a separate sport, and one for experts. The jumper takes-off down a steep slope and over a platform, which he leaves at a speed of about 50 m.p.h., to land something like 150 feet below his take-off, and more than that distance out in front of it. Ski-Joring is really ski-racing behind unridden horses, but the term is also applied to quite gentle ski-trips behind ridden horses, horse-drawn vehicles, and mechanical vehicles.

The Biathlon is a combination of skiing over a 20-kilometre course and rifle-shooting. There is a World Championship, and Britain enters for this, but the leading exponents of this sport are the Scandinavians and the Russians. As with the Modern Penthathlon (*q.v.*), most British competitors are servicemen, but the sport is in no way barred to civilians.

Bobsleigh Riding and Tobogganing consist of riding and racing down ice runs at terrific speeds on sleighs, the bobsleigh being for two, four, or five riders, and the toboggan, which takes its name, not from anywhere in Europe, but from a Red Indian language, being for one rider. Bobsleigh crews sit, the first man steering by a wheel or ropes, and the last man operating the brake

with which the sleigh is fitted. Toboggan riders lie face downwards, and brake through special spikes on their boots. Both sports are exceptionally thrilling, and both can be dangerous.

Even greater speeds, ranging from 50 to 100 m.p.h., and even greater danger, are to be found in Ice-Yachting. This sport, or something very like it, has actually been known for hundreds of years, but it is now rarely available in Europe because of the lack of frozen lakes large enough for the modern high-speed yachts. In the United States, however, there are over 3,000 such yachts to be seen during the season, which, as with European winter sports, lasts from December until March. One-man ice-yachts normally carry about 75 square feet of sail, but two-man yachts may carry as much as 650 square feet. Two-man yachts may be 56 feet long and weigh half-a-ton.

At the opposite extreme from the point of view of speed is the 400-year-old Scottish game of Curling, which is played on ice, but not on skates. It resembles Bowls (*q.v.*), but the implements used are curling stones weighing about 35 lb., and having handles. Slow, but still-moving stones are encouraged by sweeping the ice in front of them with brooms.

Not a European winter sport, but nevertheless a snow sport in Canada is Snowshoe Running. Like skiing, this is a useful method of travelling about on snow that has been made the subject of races. The Canadian side of the Atlantic is also the home of Snow Snakes, a Red Indian game that consists of throwing a polished wooden stick along an ice trough in the snow. These "snakes" have been known to go for over a mile and to travel at 120 m.p.h. (*See also* Skating.)

Wingfield Sculls. *See* Boat Races.

Wrestling.

Wrestling, an individual combat in which competitors, using only their bare hands, endeavour to throw each other, is one of the most natural sports, and also one of the oldest. It is practised in many countries, and in many different styles, in most of which the wrestlers are divided into classes by weight.

In Britain, probably the most popular style is Catch-As-Catch-Can, in which the wrestlers start apart, and may try to throw their opponents by grasping them with the hands or by various kinds of trip. During the bout, the competitors may be either on their feet or down on the mat, and the rules contain various provisions to prevent the bout lasting for an indefinite time. Wrestlers reaching a deadlock on the mat may be ordered to stand up and start again, and points decisions after a certain time are also possible. Certain dangerous holds are barred.

Another style is Cumberland and Westmorland Wrestling, which is extremely popular in those counties, and in Scotland. In this, the wrestler clasps his hands together behind his opponent's back, and all throwing is done by the legs, the breaking of the opponent's clasp constituting the fall. The initial hold is, therefore, of major importance, and the taking of it often takes longer than the actual bout.

A further form of British wrestling is Cornish Wrestling, in which the wrestlers wear canvas jackets, by which all holds are taken. A similar form of wrestling is found in Brittany.

In Græco-Roman Wrestling, which has always been very popular on the Continent, though less so in Britain, wrestlers start apart, and may take hold only above the waist. Bouts in this style may take a considerable time. At one time, there were many Græco-Roman handicap matches, in which a top-class wrestler undertook to win a fall, or a number of falls, in a fixed time.

Græco-Roman was formerly the style u professional wrestling, but, in recent year fessionals have used the "Free" or "A style. This has rules, but it is not alway clear just what they are, and this, con with widespread suspicions that bouts a really genuine contests, has led to the quit following that it retains going to see it m an amusing "stunt" than as a serious sp event. In the United States efforts to interest in it have taken the form of staging in a ring that has been turned into a sea o or that has been filled with fish. All this course, done considerable harm to the repu of what is really a fine sport and a h exercise.

Judo. Wrestling has been popular for cen in Oriental countries such as India, Chin Japan. Of the various styles, one from has won popularity in many countries, inc Britain.

This is Judo, which derives from the elaborate Ju-Jitsu. Governed largely by and with wrestlers graded according to Judo is now an international competitive but it is still often taken up as an effective m of defence against a stronger or better-attacker. Requiring a knowledge of anato consists partly of defence by knowing how and partly of attack by locks which giv opponent a choice between capitulation broken bone, and by paralysing nerve c The various locks are potentially dangerous when practising, should be released immed the opponent requests this. Also develop Japan, though it originated in China, is Ka combat system so potentially dangerous when practised as a sport, attacking moves only be indicated, and never pressed home.

Yachting.

The first recorded sailing contest was from Greenwich to Gravesend on 1 October between Charles II, who won, and his br the Duke of York. In those days, such co generally took the form of manœuvring fo tions of advantage, rather than straightfo racing, for the Royal Navy also relied on s and every privately owned vessel was a po ally useful naval auxiliary: a fact that empl the appropriateness of the right of Eng most famous yacht club, the Royal Yacht S ron, to fly the White Ensign. The clu founded as the Yacht Club in 1815, becomi Royal Yacht Club in 1817, when the Regent joined, and taking its present na 1832. In 1851 the club put up for compe a silver cup that has become the most fa trophy in yachting, and one of the most fam sport. In that year a schooner of the then fa New York pilot-cutter type, called the *Am* sailed across the Atlantic to compete in a 5 race round the Isle of Wight for the ne capturing the trophy which now bears her n

To date, there have been twenty challenge teen by Great Britain, two by Canada, an by Australia, but not one of them has succ Britain's 1958 challenge, which was the tenth, pointed the present trend in yac which is towards smaller vessels. Previous America's Cup conditions stipulated that the must be between very large yachts of the "21-metre type, and that, if the challenge was across the Atlantic, the challenger mus across. In 1958, the rule about sailing acro Atlantic was waived, and the event was be yachts of the 12-metre class.

Large vessels are still seen in the famou muda Race, but the modern trend is very e in the growing popularity of the annual Folk Dinghy Race across the Channel, which al a class for catamarans, very fast and very p boats that consist of two boats side by joined by a kind of raft.

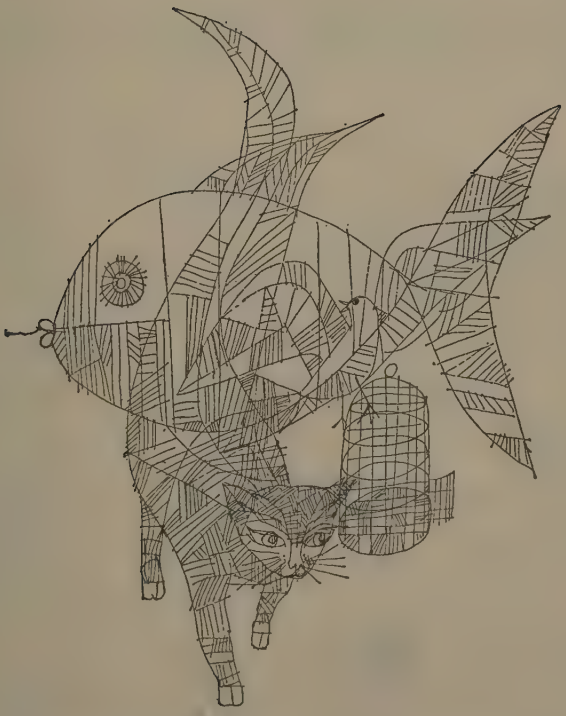
DOMESTIC PETS



DOMESTIC PETS

This section attempts to deal not with all the many hundreds of animals that may be kept as p but only with those that are best suited to average homes in Great Britain. The maintenanc monkeys, squirrels, bats, mongooses, and snakes, while quite feasible to those with experience facilities, requires considerable time and—in some instances—expense. Those who contemplate exotic pets should consult works of reference, study the methods adopted in zoological gardens, discuss the matter with experts. Even in the case of the more common animals, the informa provided in the following pages is to be regarded only as a beginning, to be supplemented so fa possible by practical experience, discussions with more knowledgeable owners, and the study of r detailed writings.

Certain considerations are basic. Never keep a pet unless you are really interested in it and prepared to give it due—and regular—care and attention. Don't keep a pet you cannot affor maintain in health and comfort. Scrupulous attention to cleanliness is essential, and wise feedi one of the most important factors in avoiding illness and loss of condition.

Since the passing of the Veterinary Surgeons Act of 1948 it is illegal for anyone to practise diagnosis and treatment of animal diseases unless he or she is: (1) a veterinary surgeon; or person whose name has been placed on the Supplementary Veterinary Register. (Certain emplo of Animal Welfare Societies are specially licensed, but it is intended that in future all animal treat shall be given by or under the direct supervision of members of the veterinary profession.) Not a pharmacist may attempt to diagnose or treat an animal. Anyone may, of course, render " aid," and an owner may—at his or her own risk—apply treatment. It is, of course, a wise precau to seek veterinary advice for any ailing animal, and the sooner it is sought the more likely it is good results will follow.

BREEDS AND VARIETIES OF DOGS.

Of recent years, dog breeding and showing have become specialised occupations, which average people cannot be expected to take up without having adequate time or resources at their disposal. Any amateur who wishes to breed for profit from pedigree animals should seek expert advice before attempting to do so.

Dogs which are intended for shows or for pedigree breeding must be registered, in the name of the owner, with the Kennel Club, 1–4 Clarges Street, Piccadilly, London, W.1.

The following are the breeds of dogs recognised by the Kennel Club for the purpose of separate Registration and Stud Book entries:—

SPORTING BREEDS

Hound Group

Afghan Hounds
Basenjis
Basset Hounds
Beagles
Bloodhounds
Borzois
Dachshunds (Long-haired)
Dachshunds Miniature (Long-haired)
Dachshunds (Smooth)
Dachshunds Miniature (Smooth)
Dachshunds (Wire-haired)
Dachshunds Miniature (Wire-haired)
Deerhounds
Elkhounds
Finnish Spitz
Foxhounds
Greyhounds
Irish Wolfhounds
Rhodesian Ridgebacks
Salukis
Whippets

Gun-dog Group.

English Setters
Gordon Setters
Irish Setters
Pointers
German Short-haired Pointers
Retrievers (Curly Coated)
Retrievers (Flat Coated)
Retrievers (Golden)
Retrievers (Labrador)
Spaniels (Clumber)
Spaniels (Cocker)
Spaniels (Field)
Spaniels (Irish Water)
Spaniels (Springer English)
Spaniels (Springer Welsh)
Spaniels (Sussex)
Spaniels Welmaraners

Terrier Group.

Airedale Terriers
Australian Terriers
Bedlington Terriers
Border Terriers
Bull Terriers
Bull Terriers (Miniature)
Cairn Terriers
Dandie Dinmont Terriers
Fox Terriers (Smooth)
Fox Terriers (Wire)
Irish Terriers
Kerry Blue Terrier
Lakeland Terriers
Manchester Terrier
Norwich Terriers
Scottish Terriers
Sealyham Terriers
Skye Terriers
Staffordshire Bull Terriers
Welsh Terriers
West Highland W Terriers

NON-SPORTING BREEDS.

Non-sporting other than Toy.

Alsatians (German Shepherd Dogs)
Bearded Collies
Boston Terriers
Boxers
Bulldogs
Bullmastiffs
Chow Chows
Collies (Rough)
Collies (Smooth)
Dalmatians
Dobermanns
French Bulldogs
Great Danes

St. Bernards
Samoyeds
Schipperkes
Schnauzers
Schnauzers (Minia
Shetland Sheepdog
Shih Tzus
Tibetan Apsos
Tibetan Spaniels
Tibetan Terriers
Welsh Corgis (C gan)
Welsh Corgis (broke)

Toy Group.

Chihuahuas (Long-coat)
Chihuahuas (Smooth-coat)
English Toy Terriers (Black and Tan)
Griffons Bruxellois
Italian Greyhounds
King Charles Spaniels
Cavalier King Ch Spaniels
Maltese
Miniature Pinsche
Papillons
Pomeranians
Pugs
Yorkshire Terriers

A separate register, called a Breed Register, is
ot by the Kennel Club for each of the above
eeds or variety of breeds. A separate register is
o kept for the following:—

ters (Crossbred)	Spaniels (Interbred)
trievers (Interbred)	Spaniels (Crossbred)
trievers (Crossbred)	

A dog which is not eligible for entry in any of the
ove registers may be entered in one of the
lowing registers kept by the Kennel Club:—

ny Other Variety	Crossbred Dogs
terbred Dogs	

The following breeds, among others, are eligible
entry in the "Any Other Variety" register:—

askan Malamute	Maremma (Italian
stralian Kelpie	Sheepdogs)
vier Belge de	Mexican Hairless
Flanders	Norwegian Buhunds
chbracke	Pedergo Iblicenco
penendaels	Polish Sheepdogs
ngarian Kavasz	Rottweilers
ngarian Vislas	Soft-coated Wheaten
sky	Terriers
land Dog	Tibetan Mastiff
panese Akita	

Any dog will be accepted for registration in the
edience and Working Trials Record, irrespective
ata ancestry, on condition that it competes only
Obedience Tests and/or Working Trials.
Challenge Certificates are issued by the Kennel
ub to certain Championship Shows for each
ed or variety of a breed of which a separate
ister is kept. A dog qualifies for the title of
ampion when it has won three Challenge Certifi-
es under three different Judges.
In the limited space available it is impossible
describe the special characteristics of the
ferent breeds. The breeds recognised in Great
itain are subject to constant review by the
nnel Club, and it is probable that the number
l continue to be added to from time to time.
The dog was probably the first animal to be
mesticated in the true sense of the word, and
e uses to which he has been put by man are
most legion. Throughout the world dogs are
ployed to help protect herds and flocks, and
leed the dog trained for shepherding plays an
egral part in sheep management. The names
xhound, Deerhound, and Otterhound all
licate the specific uses to which dogs have been
t in the Chase. Greyhounds and Whippets are
ed in coursing, and work singly or in pairs,
ther than in packs. As their names indicate,
e various Setters and Pointers are employed to
licate the exact whereabouts of game, and
aniels also are widely used as gun-dogs. The
her uses to which dogs have been put in field
orts include hunting over rough and difficult
untry by small terriers, and going to earth to
l or hold badgers, foxes, and otters. Fox
rriers, Dachshunds, Dandie Dinmonts, and
ottish Terriers are among the types which have
en so employed. Dogs have played their part
o in entertainment: thus there are performing
gs, notably the Poodle, and racing Whippets and
eyhounds, while in former times various types
fighting, including baiting of bulls by Bull-
gs, were to be seen. The use of sledge-dogs is
ll known, while in Belgium and elsewhere dogs
re at one time widely used as traction animals.
coaching days, the Dalmatian was a carriage
g, and modern scientists have recently sug-
sted, as a result of experiments, that the
sition under or behind a coach which a Dalma-
n automatically takes is determined by hered-
y! Perhaps the most exacting use to which
n has ever put dog was in China, where the
ow-Chow was once maintained as a source of
at and fur! In Portugal, fishermen employ a
e of dog to accompany their fleets. The dogs

h, and will even swim from one smack to another
convey messages! In New Guinea native dogs
t as scavengers, while in various countries on the Continent of Europe "truffle dogs" are employed to locate the fungi known as truffles, relished as a table delicacy.

The above paragraph is far from exhaustive, and for those who wish to know more of the characteristics of the different varieties of dogs, reference should be made to such volumes as *Book of the Dog* by Brian Vesey-Fitzgerald (Nicholson and Watson, London; 2 guineas) or *Working Dogs of the World* by C. L. B. Hubbard (Sidgwick and Jackson Ltd., London; 16s.) For general guidance on dog management, see *The Right Way to Keep Dogs* by R. C. G. Hancock (Elliott, Kingswood, Surrey; 5s.)

For present purposes it is, however, as a pet or companion that we are considering the dog, and it must be agreed that many of the most successful animals for this purpose are cross-breeds or "mongrels." There are many fallacies or unsubstantiated generalisations regarding the relative merits of pure-breds and mongrels. This is in fact an intricate scientific problem, and probably the simplest way of summarising the true position would be to say that, from the point of view of health and temperament, there are good, bad, and indifferent specimens among pure-bred and cross-bred animals. It is true that within a breed (or within a local community of mongrels for that matter) certain weaknesses or undesirable traits may arise from hereditary defects.

It may be noted that the word "dog" is applied to the whole species, although it is used also to denote the male as opposed to the female, for which the correct term is "bitch." Young animals are referred to as "dog puppies" or "bitch puppies" respectively. A male animal employed regularly for breeding is known as a "stud dog," and the corresponding female as a "brood bitch." In hunting circles the Foxhound is referred to as a "hound," and the term dog and bitch are employed only as prefixes to denote the sex.

CHOICE OF DOG.

However attractive the idea of keeping a dog may be, it is unwise and unkind to purchase or to accept one without very careful consideration. Dogs require regular feeding, grooming, and exercise and, if they are to be allowed to show their full capabilities, constant companionship and attention. Nothing is more pathetic than the unwanted dog, which may have been purchased because of a passing whim, and with which no one appears to have the courage to part. If, on the other hand, one is prepared to give all the necessary time and trouble to the proper care of the dog, the reward will be ample.

The size of the choice is important. Many people keep dogs which are far too large for their houses and for their purses. The smaller the dog, the less food, exercise, and house-room will he need, and the many varieties of terrier provide a range from which suitable choices for most households may be made. In any event, a very large dog should not be chosen unless expert advice has been taken about his feeding and other requirements.

Household dogs of six months of age or over must be licensed. Licences may be obtained from any post office (7s. 6d. at present).

MANAGEMENT OF THE DOG.

Accommodation.—Up till comparatively recently most dogs were kennelled down out of doors. This practice has its advantages, but today the majority of pet dogs are allowed more or less the run of the house. A warm sleeping-place, such as a box or basket, should be provided, and should contain removable bedding. Newspaper is an excellent non-conductor of heat. It is a very useful material to place at the bottom of a dog's box; and on two or three thicknesses may be placed a rug or blanket on which the animal may lie. It is astonishing the amount of grit and dust a dog can bring into a house on his limbs and the lower part of his body. His bedding will require frequent shaking out and renewal, and paper is easily changed. The box or basket in which the

dog lies should be allowed a place free from draughts, and requires airing daily when the dog leaves its bed in the morning. Wood-wool makes excellent bedding in outhouses or where a special structure is provided by way of dog-kennel, but is inclined to be messy about the house, as a dog will draw portions of it about the room as he leaves his bed. If straw is used, it is best stuffed into a sack and made into a kind of mattress. An odd piece of linoleum forms an excellent foundation to the dog's sleeping-box or kennel; it does not strike cold to the skin, is a slow conductor of heat, and has the advantage of being easily kept clean, particularly during illness, when there may be discharges and messes to be frequently cleaned up, until the animal can once more go out of doors.

Exercise.—Every dog should be exercised regularly, but there is no need to over-exercise, and the practice of allowing a dog (other than a large and athletic animal) to run behind a bicycle for mile after mile cannot be too strongly deprecated. Two or three fairly short walks a day are sufficient for a small terrier, always provided that there is a garden in which he can play on fine days and some open space where he can run freely for a short time. While still in the puppyhood stages, a dog should be trained to walk to heel and to beware of traffic. Even so, it is usually safer to put him on a lead in busy thoroughfares. One point which, to the annoyance of the public, many dog-owners fail to realise, is that their animals would show much less tendency to fight if allowed to investigate one another off the lead. A dog naturally feels aggressive if put on the lead immediately a rival hails in sight. There are, of course, certain dogs which attack others at sight; these are a public nuisance, and should never be allowed loose on the streets.

The practice of allowing a dog to take his own exercise is to be deprecated, especially in towns and suburbs. The animal will be tempted to sniff into dustbins, and, if a male, will tend to follow a bitch in season or to take part in the unsavoury "dog parties" which are so often to be seen. Furthermore, such an animal is usually responsible for the disgusting habit of fouling the pavements and gateways. In this connection, it should be emphasised that dogs may quite easily be trained to defæcate in the gutter, or on the grass verge, and so avoid contamination of the pavement or carriage-way. In some districts owners are liable to a fine if their dogs foul the pavement.

Training.—Patience combined with the gift of putting yourself in the dog's place is the chief requisite for successful education. It is most important to encourage regularity of habit, as an animal will obviously learn very much more quickly if his daily walks, meals, and grooming take place at fairly constant times. A quiet firmness is the ideal method, and a puppy should learn early that a command *is* a command, and must be obeyed. There is no need to shout and make an exhibition of oneself, or to race in circles after a disobedient puppy; if these things are done, the animal will never become so well trained as it otherwise would. Again, it is rather ridiculous to chastise a puppy *after* he has somewhat belatedly decided to come to heel: quite obviously, he will then be liable to think that he has done wrong in actually coming to heel. Whatever happens, it must never be that the dog becomes master; there is no more unbecoming sight than that of a person with a frankly disobedient dog, and if the animal be large and powerful it may prove a menace to its owner and to the public.

Puppies should be house-trained at an early stage. If care and thought are given to the matter, the animal will soon learn not to make messes in the house. However, it is very stupid to forget all about a puppy or dog for many hours, and then, out of sheer vexation, chastise it for having made a mess. If puppies are let out every two hours or so at first, they will soon learn not to make a mess. Encourage them for performing in the right place rather than scold them for doing so in the wrong one. Physical punishment should be administered only where strictly necessary, and then in a sensible fashion. The most effective method is to grasp the dog or puppy by the of its neck and to shake it.

Grooming and Washing.—Whilst short-h breeds need little or no attention to the coa an occasional brisk rub down with a bru rough towel (which incidentally puts a ple gloss on the smooth-haired breeds), yet wit long-haired breeds grooming should be c out regularly, and if the habit is made a dail it will not be forgotten so readily. Near dogs love this procedure, and most dogs actually ask for their daily groom by jumpi the table or bench on which it is carried Steel combs and brushes are sold by many s principally corn chandlers, though some chemists also provide a suitable range of g ing kit for all breeds. There is a curious current among many breeders that dogs sh not be washed. There is no reason why, w few simple precautions, a dog should no washed whenever it is socially necessary. first precaution is to use a soap that does no tain an excess of soda. The strong washi soaps, excellent as they are for certain purp are too irritant for a dog's skin. While of the toilet soaps suitable for human use m employed for dogs, the special dog soaps shampoos are much better for the purpose. are more suited to the dog's skin and coat have better detergent properties. It is impo not to have water that is too hot—as w baby's bath, it should be possible to dip the of one's elbow into the water and find th gives a pleasantly warm sensation but is bearable, *i.e.*, it should not be above 95–10 On emerging from a bath a dog will shake hi thoroughly, and then, if not curbed, will ro the floor or ground and speedily cover hi with dust or dirt! It is therefore necessa give him a brisk rub down with old (but c towelling, whereupon he may be allowed t off in a warm place free from draughts or, in weather, put on a lead and taken for a brisk In the case of many of the long-coated bree is customary to have them trimmed at the b ning of summer, and this is a sensible preca that may avoid a good deal of distress durin weather. The smaller long-haired dogs particular, such as Scottish Terriers, suffer u from the heat if their coats are grown too lo

FEEDING OF THE DOG.

Meat, usually beef, is generally regarded a staple article of the dog's diet. It mus pointed out, however, that although the d naturally a carnivore (flesh-eater), ordinary (muscle or "flesh") is not a completely ade diet, and lacks certain factors which the wil would find in the blood, bones, liver, and organs of his prey. Furthermore, it has proved scientifically that dogs can thrive meatless diet. In spite of these reservat however, meat must be regarded as an exce article of food, and if properly supplemented prove very satisfactory. In recommenda which have recently been made in America S. R. Speelman, of the U.S. Department of culture) it is suggested that meat (beef, mutton, or horseflesh, providing that the l fed regularly and not spasmodically) or substitutes (fish, milk, eggs, etc.) should stitute one-half of the daily ration, and tha remainder should comprise approximately parts of cereal substances (bread, biscuits) a vegetables (carrots, spinach, onion, beet, It is pointed out that many dogs do not accep vegetable material readily. On this basis, approximate quantities of food required by dogs have been calculated as follows:—

Weight of dog.	*Total food per da*
1 lb.	2 oz.
10 lb.	12 oz.
25 lb.	1¼ lb.
50 lb.	2 lb.
75 lb.	3¼ lb.
100 lb.	4¼ lb.
150 lb.	5½ lb.
225 lb.	7 lb.

(Weights of up to 10 lb. would include the toy breeds, 25 lb. would correspond to a Fox Terrier; Airedale Terriers and Retrievers would fall into the 50–75-lb. class, and the larger weights would be those of the very big breeds, such as the St. Bernard.) The quantities given are, of course, an *approximation* and no more. Dogs which lead a very active life will require more, while those which take little exercise, or which tend to put on fat easily, will require less. Common sense is necessary, and great care must be taken not to over-feed or to under-nourish.

Meat is probably best fed raw, or lightly cooked, but many animals appear to have a preference (probably through habit) for well-cooked meat. In any event, the meat should not be "overdone," as there is substantial evidence that prolonged heating destroys much of the food value of the meat protein. *Fish* is an excellent substitute. There need be no anxiety about the greed with which a dog swallows lumps of meat and also neglects to masticate them. The juices of the dog are for tearing meat, he is not concerned with biting his food up small; indeed, his salivary glands contain no digestive ferments, as is the case with some other animals.

Milk is almost essential during pregnancy and lactation (see below), and may well be included in normal dietaries. Whether or not *bones* should be fed is a matter which has been hotly debated, but for mature household dogs the evidence suggests that they are unnecessary. (The teeth of racing greyhounds, which receive a "slipper" diet, are quite as good as those of the average household dog.) Bone-feeding is responsible for much trouble, including constipation, actual impaction of the rectum, and lodgement of pieces of bone in the mouth or throat. The value of bones is, of course, that they contain large quantities of essential mineral substances, and for this reason the inclusion in the diet of bone-meal, or of steamed *bone-flour*, or, preferably, a mineral supplement, is recommended. Only very small quantities of these substances are required.

Bread is an article of food which is often overlooked in the case of the dog, but there is no doubt that wholemeal bread is very suitable indeed, provided it is not fed to excess.

The answer to the question whether a dog requires vegetables is, in the main, no. From the Vitamin C standpoint they are quite unnecessary, since it has been shown that a dog manufactures this vitamin for itself, but the fact remains that many dogs, particularly of the toy variety, enjoy a few slices of banana or apple, and there is no harm in letting them pander to their taste. Vegetables do help, however, to provide roughage, and cooked (not raw) *potatoes* may be used in place of bread or biscuits. The dog—like many other animals—cannot digest raw starch properly. *Flaked maize* and *oatmeal* are other substitutes, but it must be remembered that the energy value of maize is high and that the dogs must never be overfed. *Dog biscuits* are an item that were long is disfavour with some professional people on account of their often having been made from agenised white flour (see section on Canine Hysteria), but now that this factor has been overcome, and the biscuits themselves are being improved in other ways, their use for the non-meat portion of the diet may be recommended.

Clean fresh *water* must be provided at all times.

In addition to the diets recommended above, there are on the market several tinned dog foods which claim to be complete, or almost complete, diets for the dog. It must be said that many dogs (including those of the writer) have remained in excellent health when receiving one of these foods as a large part of the diet over long periods. There is, therefore, little that may be said against the widespread use of the better varieties of such products. Again, it is a matter for common sense; if an owner finds that his animal is thriving on such a diet, he is wise to continue to use it.

It is customary to give dogs two meals a day. There is no need to give more than two to healthy adults, for the dog's stomach is exceedingly capacious and adapted to long gaps between meals. Many dogs thrive on only one meal in twenty-four hours. Whatever plan is decided on, regularity should be adhered to, and a meal or meals given at the same times every day.

Dogs require vitamins A and D and B complex. There are several ways of administering these, but the special commercial preparations, including the modern form of condition-powder tablet, are the most convenient.

The *pregnant* and *lactating bitch* require special consideration. The food requirements are very much increased in a bitch which is carrying puppies, especially towards the end of the period. Normally, appetite is not a complete guide to a dog's food requirements, but in pregnancy and lactation the bitch must not be allowed to go hungry. It is quite normal for a heavily pregnant bitch to require over one and a half times her normal amount of food, and in lactation her requirements will increase still further. Milk is a most excellent article of diet at this time; indeed, there is no better way (apart from commercial preparations) of replacing the milk which the bitch is giving to her own puppies.

Up to the age of three weeks or so, *puppies* need have mother's milk only, but at any time after this it is a sound policy to give them additional food, and so spare the mother and also render weaning (at from six to eight weeks) a *gradual* process. At first a little cow's milk or one of the commercial "dog-milk" preparations may be given, and gradually the puppies should be encouraged to eat solid food. Eggs (if they can be spared), wholemeal bread in milk, or even finely minced meat may be given, at first in very small amounts but later in larger quantities. If this process is carefully carried out, there will be far less trouble at and after weaning time. After weaning, puppies should receive five or six meals a day, and this number may be cut down gradually until two or three only are given to the fully grown dog. (The smaller breeds are fully grown at about a year.) *More* meat or meat substitutes and milk, and *less* cereal or vegetable matter, should be fed to the growing dog as compared with the adult. This fact is important, as the substances present in meat and milk are required for laying down the growing tissues. Nevertheless, the energy portion of the ration is important, and the cereal or vegetable should be nutritious and not fibrous. It is possible to rear puppies by hand from birth if the bitch for any reason should die. It requires great patience for the first two or three weeks, as naturally the puppies will require feeding once or twice during the night. Special milks for puppies are to be recommended. Cow's milk requires enriching with fat and sugar to approximate to the composition of bitch's milk. Feeding will have to be done at every two or three hours, and a very useful gadget is a fountain-pen filler attached to cycle-valve tubing. Very small quantities are required for the first two or three days, and a level teaspoonful of milk is more than sufficient for the average terrier at first. Even with the best care in the world hand-fed puppies tend to be weaklings and do not grow as fast as those naturally fed. A foster bitch, if obtainable, is much to be preferred.

BREEDING OF DOGS.

It is natural for adult dogs of both sexes to wish to breed, and in the case of the female especially it is an excellent thing if one can arrange for a suitable mating to take place. Bitches come "into season" or "on heat" (lay terms for œstrus) at approximately six-monthly intervals, but it is not advisable to breed from the first season which occurs usually at about eight to nine months of age, but over a wide range of age according to breed and other factors. The periods of season often occur between January and March and in early Autumn, but there is no fixed rule. Each season lasts for three weeks. For the first seven days, approximately (pro-œstrus), a bitch does not permit mating, though during this time she is a source of strong attraction to all males in the neighbourhood. At about the seventh to the tenth day the blood-stained discharge, which ushers in the heat, stops; this is usually taken by the breeder as an indication that the bitch will stand to service. If possible, it is always better when puppies are wanted to allow mating to occur more than once. Under natural conditions a dog and bitch are usually strictly monogamous and mate for life, and during the period

of œstrus will mate many times. A dog and bitch that are kept together all the time will probably behave naturally, but under domestication both dogs and bitches usually become promiscuous. Many bitches will in fact accept service from different males on different days, and the phenomenon of superfecundation, i.e., the production of a litter that is fathered by *two* males, may occur. It is therefore wise to retain strict control of the bitch throughout the whole of the three weeks or so she is in season. At the end of season the bitch passes into a state of " metœstrus " if she has not conceived.

If a bitch conceives, she carries her puppies for a period of about nine weeks. There is, however, a normal variation of fifty-eight to seventy days, and puppies born before the fifty-eighth day sometimes live. The number of puppies born varies with breed; in the smaller terriers it is usually from four to six, but in Airedales and Alsatians the number may be eight to ten, and the larger breeds tend to have even more offspring at a time. Birth usually takes place fairly easily in the larger breeds, but there is often much difficulty in the case of the short-legged breeds, such as Scottish and Sealyham Terriers, Pekingese and Dachshunds. In some breeds, in fact, the problem is one that is giving serious concern to veterinary surgeons and breeders.

A short while before her puppies are due, a bitch will " make her bed." Owners are often amazed at the destruction of soft furnishings, or even of wall-paper, that a previously well-behaved bitch may carry out at this time; it is therefore by far the best to provide a suitable box (if the animal has not one already). A smooth flooring such as a strip of linoleum serves for the bitch to give birth to her puppies. Her instinct to tear up everything given to her for bedding may lead to suffocation of the puppies by pieces of bedding. Provided labour occurs in a warm room, it is sometimes better—according to the temperament of the bitch—to remove each puppy as it is born, placing a warm bottle underneath, and bring it back to the mother when the last birth has occurred. At this time the bitch should be watched carefully for any discharge from the vulva or for any evidence of straining. If either of these occurs without results, it is advisable to send for help as early as possible, especially in the case of the smaller breeds. Many hundreds of bitches are lost through neglect at this time, and usually because it was not suspected that anything was wrong. If the discharge becomes bloody, or green, help should be obtained *at once* if no puppy is delivered. Similarly, any great delay between births is a matter for concern. The afterbirth usually follows the puppy within a few minutes, but puppies are sometimes delivered in their foetal membranes, and in this case the latter should be gently but quickly removed. It is quite normal for the umbilical cord to remain attached to the puppy, but the bitch will normally break it by biting through it.

The mother will wash and attend to the new born puppies, and after the last is born it is a good idea to burn all the mess and to provide clean newspaper, but do not worry or frighten the bitch more than is necessary. For the care and feeding of the bitch and her puppies see the sections on Management and Feeding. Puppies, like kittens, are born with their eyes closed, but open them after about nine days—there again being considerable variation.

The phenomenon of pseudopregnancy is common in bitches, and indeed to a minor degree it is probably present in most bitches following an œstrus without conception. In some bitches, however, presumably those with strong maternal drives, the changes in the ovary may be accompanied by external signs of " phantom " or " ghost " pregnancy. These may include not only enlargement but actual functioning of the mammary glands, and the making of a " nest " by the bitch just as if her puppies were really due. The average duration of pseudopregnancy is usually given as about two months, and although variable, it is often sufficiently near to the correct time after œstrus that everyone suspects the bitch to be truly pregnant. The condition may be suppressed with the aid of modern drugs, but in some instances it is not realised that the condition is not real. In many cases only professional advice can solve the mystery, and radiographic examinations have often proved necessary to ascertain the truth, particularly in fat bitches of the heavier breeds. It might be well to note, at this point, that there is another condition of the older bitch that is known as *Pyometra*. This condition usually reveals itself at the same time as the ghost pregnancy (and is sometimes a pathological extension of it) but is accompanied by considerable disturbance of health, coupled in many instances with purulent discharge from the vagina. A bitch which is off-colour in the week following pregnancy, or which develops a discharge from the vulva (especially one which is dark in colour), may well be a pyometra subject. This disease is most serious, and often requires surgical intervention. As the best chance of success is to operate or otherwise deal with early, a veterinary surgeon should be consulted immediately.

DISEASES AND INJURIES OF THE DOG.

Canine Distemper and " Para-distemper (Including so-called " Hard-pad ").—It has long been recognised that the commonest and most serious disease of dogs throughout the world is canine distemper. Dogs of all ages and breeds are susceptible, and no dog is free from the risk of infection unless it has recovered from the disease or has acquired an immunity for other reasons (*see* P8(2). The disease is caused primarily by a minute agent known as a filtral virus (*see* P7(2), which may be of varying types that it will attack the body in different ways. Thus some strains of the virus are known as " neurotropic " because they show an affinity for the nervous system. Sometimes a dog will apparently recover from an attack of distemper only to succumb later to " fits " or other nervous manifestations due to permanent damage to the central nervous system by the virus. Often, however, the virus is not fatal in itself, but will lower the dog's resistance and permit the entry or the activity of bacteria that may lead to pneumonia or other serious effects. These are called " secondary invaders," as the bacteria are termed, may prove as harmful as the original virus. Indeed, once these bacteria have set to work it is too late to expect the best results from the use of serum, and whether or not the dog will live through will depend upon the severity of the attack, the dog's powers of resistance, and good nursing. It is therefore most important either to prevent the disease by vaccination or to be able to send for veterinary attention (and help for an injection of serum) *immediately* an attack is suspected. Any puppy which is listless or off its food, or which may throw a fit, or which is obviously unwell with other symptoms (*e.g.* a cough or diarrhœa) may well be in the early stages of distemper, and it is *then* (not the next day) that help should be sought. Many thousands of puppies (and older dogs) that have been injected become perfectly normal within four hours. On the other hand, the number of dogs that die in Great Britain alone from distemper and distemper-like infections must assume enormous proportions. Distemper is a highly infectious disease, and it is important that the owner of an infected animal should do his best to avoid contact with other dogs, ferrets, or mink. Ferrets and mink are very susceptible to canine distemper. On the other hand, human beings and cats are *not* susceptible to canine distemper, and the so-called distemper of cats is quite a distinct disease.

A highly satisfactory means of vaccinating puppies against distemper was worked out about 1926–30, and this—named the " Laidlaw–Dunkin " after its two inventors—has since afforded protection to thousands of animals. Modern vaccines are based on a virus which has been modified by growth on developing egg embryos or, more recently, in tissue culture. Puppies should be vaccinated when they are 10–12 weeks old prior to this age the immunity induced by the vaccine may not develop satisfactorily. After vaccination the puppy requires some time, possibly 2 weeks, before an immunity is established. Sometimes vaccinated dogs suffer distemper

stemper-like signs due to "secondary invaders" using disease on their own account; or because ey were already infected when vaccinated. ariants of distemper of which "hard pad" is an ample may also overwhelm a vaccinated dog's mmunity, although this is uncommon with modern accines, since several distemper strains are used their production. Hyperimmune serum, hich is collected from animals previously yperimmunised against distemper, is available nd can immediately aid the dog suffering from stemper but its effect is short-lived (7–10 days).

Infectious Hepatitis or Rubarth's Disease.—nother virus disease of dogs (and foxes) is known Rubarth's disease, after one of its discoverers, ow known as infectious hepatitis. This disease as been recognised in Sweden ever since the 1930s, at in Great Britain only since the end of the war. he condition is extremely sudden in onset, and an ffected dog may be found dead. Many cases are, owever, mild, and in some instances only one two out of a large group of dogs have been ffected. The changes seen after death vary, but he findings in the liver cells are usually character-tic. Specific treatment is not yet established in the case of the distemper-like conditions, though the administration of antibiotics (*see* P9) ay prevent the effects of secondary infection. n effective vaccine is now produced and often ombined with the distemper chick embryo accine. A dog is thereby protected against both ese diseases.

Canine Hysteria (called "fright disease" or running fits" in the U.S.A.) is an alarming it not necessarily serious condition (in that it can ten be cured very readily) which appears to ise from a variety of exciting causes. The ffected animal rushes around wildly, often reaming and howling, and obviously loses all nse of wheabouts or ability to recognise eople. After a more severe attack (and there are l degrees up to a full epileptiform fit) the dog ay appear quite exhausted, but returns to ormal. Sometimes there are many attacks in ne day. The dog will not wilfully attack people uring a bout of hysteria—at least, that has een the experience of the writer—but is very ifficult to control. Apart from ensuring that he dog does itself no grievous bodily harm, here is little that can be done until the attack as subsided. Then the animal should be kept quiet as possible and given a tranquiliser.

Hysteria may be an hereditary taint, derived om one or other parent. In certain circum-ances, however, it may arise in apparently ormal animals. There are several possible auses (including parasites), but a definite one is he bleaching agent—nitrogen trichloride or agene"—employed for some years in the anufacture of flour, and hence present in white read and certain dog biscuits. Indeed, the ear demonstration that agene could set up ysteria in dogs, and subsequent scientific work, as led to the introduction of regulations that ave led to its abandonment as a bleaching gent in favour of other methods which have een found not to cause hysteria. There has eady been a marked decline in the incidence of ysteria due to dietary factors.

Rabies is a fatal disease of dogs, and is also due o a "filterable virus." It is transmissible to the uman being and to many other species, but has rtunately been absent from Great Britain for any years. Stringent precautions are taken to revent its entry, and dogs which are brought to Great Britain must spend a long period in uarantine. A vaccine is available and people aking dogs to countries where rabies occurs hould have their animals protected. Many ountries insist on this prodceure.

Tonsilitis appears quite frequently in dogs and eems in many cases to be part of a more general-ed infection. It demands expert treatment, but though it may persist for a long time, it usually ields to treatment.

Nephritis.—Inflammation of the kidneys is unfortunately all too common in dogs, and in adult males in particular there is a high incidence of chronic kidney damage. One of the symptoms is a marked thirst. Sometimes this condition is a sequel to an infection known as *leptospirosis*, which calls for prompt veterinary treatment if death or permanent damage is not to follow. It is always worth while seeking professional advice for a dog that drinks excessively or has a some-what characteristic type of bad breath. A vaccine which gives a good immunity against the two common forms of *leptospirosis* is available.

Anal Glands, which are found in the dog and in other carnivora, often give rise to trouble. Ani-mals which "rub themselves along the ground" are not necessarily affected with "worms," but with impaction of these two little glands, which are situated one on each side of the anus. They secrete a peculiar dark-coloured, very offensive fluid, which sometimes is not discharged properly and causes the animal great discomfort. The glands in such cases should be relieved periodically. Those who do not mind this somewhat dirty task may perhaps learn how to do it themselves. Occasionally, segments of tapeworm are respon-sible for the impaction, but usually the trouble has nothing to do with worms. Whenever a dog pays considerable attention to his anus, this im-paction should be suspected. Actual infection of the glands is also fairly common, and demands expert attention.

Diseases of the Ear, especially of the outer ear, are very common in dogs. The dog's outer ear is somewhat more complicated than is our own, and the drum is set more deeply. Hence it is easy for wax and dirt to accumulate, for various parasites to establish themselves, and for in-flammatory conditions to result. The word "canker" (which has no precise scientific mean-ing) is sometimes applied by lay people to the more serious or chronic forms of inflammation of the outer ear canal. It is not difficult to diagnose "ear trouble," as the affected animal usually shakes its head or worries or scratches its ear and rubs it along the ground. The ears should be inspected regularly to see that there is no great accumulation of wax or dirt. Cotton-wool twisted on to the end of a match-stick or orange-stick is quite satisfactory for cleaning out the ear, providing care is taken. A dog which is continually worrying its ear, or which has ears which are obviously diseased, should not be neg-lected, as the sooner expert treatment is begun the more readily will the condition be cured. Even if the lining of the ear is greatly thickened through inflammatory reaction, and the lumen nearly occluded, it is still possible for a plastic operation to be performed. Many hundreds of such cases have been successfully treated in this way. A percentage of inflammatory conditions of the outer ear is associated with ear mange mites. In such an event treatment with modern anti-mange preparations should be carried out.

Deafness in certain white dogs (*e.g.*, in some Bull Terriers) appears to be hereditary, and is quite incurable. Old dogs often become deaf, and deafness has been produced experimentally in young puppies by feeding them on a deficient diet.

Diseases of the Eye are very common in dogs, and are often the result of injury. Except for minor discharges from the corners of their eyes (and in younger dogs especially it must be ascer-tained that these are not a symptom of distemper) any eye disease is sufficiently serious to merit professional advice. Boracic lotion is not suitable for the eyes of dogs. It is slightly irritant, and dogs are apt to scratch and make the eyes raw after application. Colloidal silver eye lotions and ointments are far more suitable pending the advice of a veterinary surgeon. In eye inflammation avoid sunlight and wind. For some days in the early stages of inflamed eyes, the light in the room should be subdued. Pekingese seem to be especi-

ally prone to eye disease, but the remarkably unwholesome appearance of some affected eyes in this breed is not necessarily evidence that recovery is unlikely. Steps should be taken to ensure that the dog does not inflict further injury on an already diseased eye. Cat scratches are a frequent source of inflammatory conditions of the dog's eye. Eyes must never be neglected, for the consequences are serious.

Skin Diseases are common in dogs, and may be contagious. Among the common contagious causes of skin disease are lice, mange mites and fleas. Lice and mange mites (except for demodex) are killed by modern insecticides such as benzene hexachloride (gammexane) although two applications at a 10–14 day interval are required to destroy the young stages which are within the insecticide-resistant eggs at the first dressing. The flea actually on the dog, is only one of four stages in the life cycle of the flea; the others are in the house or dog's bedding. Insecticides used for flea control should therefore be applied every week or 10 days during the summer to kill the young fleas as they hatch and infest the dog. The dog's bedding should be discarded or cleaned. The dog also suffers from other skin diseases caused by systemic disorders for which expert attention is required.

Diseases of the Teeth and Gums are very common in household dogs. A serious systemic disease, such as distemper, may leave the enamel of the teeth permanently pitted, hence " distemper teeth." More serious than this, however, is a form of pyorrhœa, which is really a disease of the gums rather than a primary disease of the teeth themselves. The margins of the gums become red and swollen, and may bleed easily. As the condition progresses the teeth may become loosened. Particles of food become lodged between the teeth or between teeth and gums, and add to the inflammation and to the smell of the breath.

This disease may, if unchecked, become very serious. In many cases extraction of one or more teeth is indicated, but unfortunately it is not always possible to do this. The condition demands expert attention.

Another common condition of dogs' teeth is the deposition around them of " tartar." This should be removed by scaling or by special use of dental forceps. Some breeders and others may themselves have learnt how to carry out these operations with the requisite skill and care, but they are not easy to the amateur, and it is essential that no harm be done to the animal's soft tissues by injudicious use of the instruments. Ordinary dog-owners are strongly advised to take their dogs to a veterinary surgeon in order to have the " tartar " removed.

Most puppies lose their first or " milk " teeth quite regularly between the ages of three and five months, but sometimes there is difficulty and the primary teeth are not shed properly. These cases should be treated by a veterinary surgeon before the permanent teeth are thrown out of their proper alignment.

One hears very much about " teething fits " in puppies, and while these occur, owners should be very careful to ensure that a " teething fit " is not a sign of distemper, which often starts with a fit. As puppies of this age are so susceptible to distemper, it is advisable to seek professional advice should any form of fit occur. It may save much time, money, and trouble, and even the animal's life.

Internal Parasites: " Worms."—It is probable that more nonsense has been talked and written about " worms " in dogs than about any other canine subject. According to some people, " worms " are the root of nearly all doggy evil, and so long as a dog is regularly " wormed " all will go well with him. These beliefs are frankly absurd. The real facts are very different, and are stated in as brief a fashion as possible in the following sentences. In this country dogs are infested by a species of " roundworm " (a crea which is a dirty-white colour and in shape so what resembles the common earthworm) and several species of " tapeworm," which are whitish but which are flat and are made u many small segments joined to a little " he which is attached to the lining of the gut. spite of all that is said, tapeworms as such rarely responsible for much harm to the although they can, of course, prove debilita and should be removed. They are a nuisance, attempts to remove them should be made by ministration of the appropriate drug. C sionally, segments of worm are responsible impaction of the ducts of the *anal glands* above).

The roundworms may be extremely seriou young puppies, in which they cause stun " pot-belly," harshness of coat and dangerou fatal illness. Fortunately, modern anti-ro worm preparations are available for anima this age. Once over the age of 4–8 months rarely suffer serious illness from roundwo although these may cause occasional vomitin even diarrhœa, and some loss of coat and bo condition. It is now known that puppies infected before birth from their mother. therefore desirable to keep down the incid of roundworms in the mother—and in generally—and fortunately the modern prep tions are—unlike some of the old-fashioned on safe in use and unlikely to cause digestive di bances. From all that has been said a owners will realise the necessity of taking fessional advice about young dogs which ar and any signs of " worms " in young pupp either in the stools or by some obvious intes upset or bloated appearance of the belly—sh be acted upon. One last word about this a of worms—do not assume that your adult has " tapeworms " unless you see some evid in his stools. There are so many " sign worms " that veterinary surgeons must at t get a little tired of being assured that " My has worms " because of some trivial habit nected with appetite.

There is, however, another side to the stud tapeworms, and one which is not gene realised. The tapeworm which is found in dog represents one stage in the life-cycle. eggs, which are present in the ripe segment p by the dog, develop, not in the outside world in another animal altogether. Thus one o commonest tapeworms in this country ha intermediate stage, as it is called, in the and it is when the flea is eaten by the dog this intermediate stage develops further to be a tapeworm. Another tapeworm has an i mediate stage which develops in the sheep, a third has one which develops in the ox. T is a fourth tapeworm which has an interme stage which *may* develop in man, so se serious diseases in certain cases. Children become infected through handling the dog, so picking up the eggs, which may then be through putting the hands in the mouth. dogs which are most likely to be infested are which have the opportunity to eat freshly k sheep and other food-animals. An ordi household dog is not likely to be infested, people should not worry unduly in this co tion, provided they do not allow their do stray into the wrong places. It is illeg allow dogs to enter a slaughter-house, but fortunately one often sees dogs in such p The routine worming of dogs is justified if evi of infection exists, and certainly in country where opportunities of tapeworm re-infection be plentiful.

Tumours, including malignant tumours (" cers ") are relatively very common in the d probably as common as in the human sub Space does not permit of a detailed account the following examples of growths may be tioned: a proliferation of warts on the sk puppies (usually disappear spontaneously true cancer of the tonsil in middle-aged and dogs of both sexes; cancer of the mam glands in bitches (both incurable); fatty gro of the vagina of bitches (amenable to operati

Space does not allow of the discussion of

iseases, but it should be pointed out that dogs are usceptible to human and bovine forms of *tuberculosis*, especially the former. In a household hich contains a tubercular person, the dog hould be watched for any signs of illness, and he thought entertained that he might be responble for the further spread of the disease. For a iscussion on ringworm see the appropriate headg in the section on the cat (Z12).

Accidents and Injuries.—In these days of wiftly moving motor transport, street accidents o dogs are extremely common. Many could be revented by training the animal to walk to eel, by the use of a lead in busy thoroughfares, nd by not allowing dogs to roam the streets naccompanied—a thoroughly bad habit. Sometimes the victim escapes with a scare and a few ruises, and at others death is mercifully swift. n the vast majority of accidents, however, a nore or less serious injury is incurred, and if the nimal is unable to move, the police should be otified immediately. The dog is best left quiet, nd it is not recommended that attempts be ade to administer brandy or other supposed timulants" unless help is markedly delayed. Excessive haemorrhage may in some instances e prevented by common-sense application of rinciples learnt in first-aid courses.

One of the commonest accidents to dogs, specially to young dogs, is a fracture involving he head of the femur, or thigh-bone. Inability o put one of the hind legs to the ground, or to bear ny weight on this limb, is an indication of such n injury. (This injury may occur also from alling off a chair or wall.) Professional help is, f course, required in such cases.

Cuts and Bruises, if not serious, may be treated t home as in the case of human beings. The ndiscriminate use of tincture of iodine is not to e recommended, and spirit alone makes a more atisfactory dressing in most cases. Simple washing and removal of dirt are usually sufficient. Combined, perhaps, with modern antiseptic ointments or other preparations. The dog (and also he cat) are very liable to sepsis, and it is best in uch cases to send for proper assistance early, or here may be grave trouble. It is probable that n nature many of the flesh-eating animals end heir lives as victims of the sepsis following wounds.

Injuries from cat-scratches are exceedingly ommon, as are bites from other dogs. These re serious, as they more readily result in septic laces. The scratch or bite sometimes penetrates quite deeply, leaving a pocket which fills p with pus. This pus may spread under the kin to form sinuses. Never neglect such places.

Conclusion.—There are a few concluding remarks n the treatment of the diseases of the dog:—

(1) It is not correct that "water should be withheld from a sick dog." It is true that an animal which is using water only to vomit, or which is drinking excessively, should have its water intake restricted, but it is wrong to deprive a dog altogether. It may be suffering from diabetes and should be taken to the vet for testing.

(2) There have been such wonderful advances in the field of veterinary anaesthetics that there is nowadays little to fear in this connection from operations to dogs and cats. The records over the past years at the Royal Veterinary College, London and at other centres have been most encouraging, and the anaesthetic risk is now small indeed.

(3) When a dog's life is a burden to him, it is unfair to keep him alive, and he should be put to sleep. It must be realised, however, that putting a dog to sleep is a very skilled task. It is made much easier if an owner will allow his veterinary surgeon to administer an anaesthetic and not allow the animal "to come round," and shooting is also straightforward and painless if *skilfully* carried out. There are no "magical ways" of destroying human or animal life, and an owner must not expect his veterinary surgeon to be able to bring about death merely by holding a pad to the dog's face. It is far better that the task be carried out at a veterinary surgeon's own premises, where there is skilled assistance.

CATS.

Many of the general remarks in the preceding section apply equally to cats, and will not be repeated unnecessarily in the following paragraphs.

BREEDS AND VARIETIES OF CAT.

The following breeds and varieties are recognised for registration purposes by the Governing Council of the Cat Fancy:—

Long-haired Cats.

Black	Tortoiseshell
White (Blue-eyed)	Tortoiseshell-and-White
White (Orange-eyed)	Blue Cream
Blue	Brown Tabby
Red Tabby	Chinchilla
Red Self	Smoke
Cream	Silver Tabby

Short-haired Cats.

Black	Spotted
White	Russian Blue
British Blue	Manx
Cream	Abyssinian
Tortoiseshell	Siamese (Seal-pointed)
Tortoiseshell-and-White	Siamese (Blue-pointed)
Silver Tabby	Siamese (Chocolate-pointed)
Brown Tabby	
Red Tabby	Burmese
Mackerel-striped Tabby	

Pedigree breeding and showing are practised with a very small fraction of the total cat population of Great Britain, and the majority of these remarks will be concerned with the ordinary household cat. Nevertheless, in recent years there appears to have been a considerable increase in pedigree cat breeding. Registration—which is essential for showing and pedigree purposes—is controlled by the Governing Council of the Cat Fancy. Many of the breeds listed above have their own societies, which are affiliated to the Governing Council. The addresses and particulars of these and other cat societies and clubs may be had on application to the secretary of the Governing Council. The two most popular varieties of cat are the Blue Persian and the Siamese, and an exclusive show is held for each of them. In addition to these shows there are five big Championship Shows open to every variety of long- and short-haired cat, while there are classes for cats and kittens at some of the Agricultural Shows.

CHOICE OF CAT.

Although there are, as noted above, many varieties of cat, most people are content to accept an ordinary kitten, and for them the chief points to consider will be: (*a*) whether to have a long-haired or a short-haired animal, (*b*) whether to have a male or female, (*c*) whether or not to have the kitten "doctored" (*i.e.*, castrated or spayed). As a general rule, short-haired cats are probably more suitable for the average household, since their fur does not become shed so noticeably and they probably suffer less from "fur-balling." Nevertheless, many long-haired cats are so attractive that they will obviously be preferred, and there is no reason why they should not be chosen. Sex is a rather more important question, although, as may be seen in the section on management, it is possible to have both males and females "doctored." Male cats which are kept as entires are often a nuisance in that they make abominable smells in the house and spend much of their time in fighting. These characteristics are by no means invariable; but they are so common as to justify the castration of the majority of males. Siamese males in particular may be a liability. Females are generally credited with a greater attachment to the home (although they wander when "in season") and with being better mousers. The principal objection to females is that they seem to be bearing kittens almost continuously. In normal circumstances it is, of course, quite impossible to prevent cats from mating by keeping the female in confinement

during her season, a practice which is frequently adopted in the case of the dog. For one thing, most people are never aware when their female cats are in season.

Whatever animal is chosen, it is essential to pick a healthy and preferably a fairly young—but *not* too young—kitten. It is best not to accept a kitten under about eight weeks of age.

For those who wish for something a little out of the ordinary, Siamese cats make excellent and highly intelligent pets. Siamese kittens are born white, but gradually develop their even pale fawn colour, with cream on belly and chest and with "seal brown" mask, ears, legs, feet, and tail. The coat is very short, and the eyes are blue. There has long been a popular belief that Siamese cats are delicate creatures, but the present writer has seen healthy specimens, kept under ordinary household conditions, living to a mature age. It is not wise to keep a male Siamese as a household pet. The male is a fierce fighter, and is generally a worse offender in the house than the males of other breeds, and should therefore be castrated if it is to be kept as a pet.

Many people find Manx cats attractive. Instead of the normal large number of tail bones, they have but three, and hence appear almost tailless. One should beware against fraudulent amputation of the tail of ordinary cats, which are then described as "Manx."

MANAGEMENT OF THE CAT.

The cat is an independent creature, so much so that one may say that to a large extent it manages its own affairs. This, however, is not true of all cats, and every reasonable attempt should be made to provide the cat with a comfortable and friendly home. Cats are highly intelligent, and if sufficient patience is exercised they will respond to a very great degree to human attention. Kittens should not be neglected, but should be talked to and played with just as are puppies. Many cats, especially young cats, make excellent playmates for children.

In order to prevent to a large extent their nocturnal wanderings, many cats of both sexes are castrated or spayed (the popular lay expression for this is "doctored"). In the male cat the testicles are removed by an operation which is almost always safe and simple if carried out skilfully. From three to four months is a good age at which to have this done. Female cats may also be "doctored." As the female glands or ovaries lie within the body cavity, this operation is a major one, but it is nevertheless quite a straightforward, though a more expensive, procedure if conducted at the right age (about five months). Very many thousands of female cats have been so operated upon and the subsequent health of these cats has been excellent. Indeed, it has been said that a spayed female makes one of the best of all household cats.

Cats may choose to sleep in a variety of places, and will often lie on beds, chairs, mats, and other warm places. It is a sound policy to provide them with a box or basket, and to encourage them to use newspaper as a bedding. Most cats will take well to newspaper. The bed should be placed in a warm site—it is of little use putting it in a cold corner of a room and expecting the cat to lie in it.

Owing to the fact that, even in play, a cat's claws may inflict serious injury, dogs and cats do not always make the best of house companions. Nevertheless, the traditional enmity of cat and dog is often overcome, and if the two are brought up together they often make firm friends, sharing the same basket or hearth-rug and feeding together without serious consequences.

A cat normally attends to its own toilet, and everyone must be aware that a cat devotes long periods each day to cleaning and washing itself. Except in special cases, therefore, bathing is quite unnecessary, while in short-haired cats especially, grooming, too, is superfluous (this does not apply to show-cats). For some reason (and sometimes, apparently, because an owner attempts to assist in the daily grooming) an occasional cat may cease to wash or care for itself. Such an animal is a dejected sight, and should be taken to a veterinary surgeon to have its matted fur cut or combed, and its dirt removed. Such animals (unless they c pletely re-acquire their self-respect) must groomed regularly if they are to be kept at al

All household cats are accustomed to take t own exercise, and it is advisable (except in special circumstances) to allow them free ac to and from the outer world. Do not shut cat in the house for a long period and then bl it for making a mess. Cats are clean creatu they normally dig small holes in which to defe or urinate, and subsequently cover the dep with earth. If, therefore, they are for s reason debarred temporarily or permanently access to a garden, they should be provided a box or tray containing soil or cinders. Ind in many types of houses it is a good pla encourage kittens to use such a device. (Note corresponding remarks about puppies.)

It is generally stated that "cats never fo a blow," and for that reason it is recommen that cats are not chastised. It may be said t if a cat (or dog) be brought up conscientiously well, it should never, or very rarely, require punishment. An animal which has been bro up properly seems to develop a fair sense of w is right and what is wrong.

For pedigree cats, or those kept in confinem for other reasons, see the relevent remarks in section on breeding.

FEEDING THE CAT.

Although most cats are capable of supplem ing their diet by catching small rodents or bi it is unwise to rely on this as a regular sourc food. The idea that hungry cats make the mousers is by no means always correct. Ind animals that are in poor condition are less li to be successful hunters. Moreover, while riddance of pests is an excellent matter from human point of view—and one of the reasons the keeping of cats is economically justified—"cruel" fashion in which most cats tackle t prey is repulsive to most of us.

It is therefore necessary and desirable to pro regular daily feeding. Kittens should rec several meals a day, but by the time they six months old the number of daily feeds sh be reduced to one, or at most two. Most (many Siamese are exceptions) are extremely f of *milk*, especially if it is creamy, and the c love of *fish* is well known. Many *meats*, especi *rabbit meat*, are relished, and a diet high "animal protein" is indeed the aim, alw provided that it contains sufficient "die energy." It is significant that cat's milk h higher content of fat and sugar than cow's m *i.e.*, it is a richer source of energy. Some of proprietary bitch-milk substitutes are neare cat's milk in composition than is cow's milk.

Many hundreds of cats have been reared bred successfully in experimental laboratories a diet consisting, in the main, of one part of or meat and two parts of *cooked potatoes*. is relatively inexpensive, and may be sup mented by milk and by some of the proprie t foods.

Cats are also extremely fond of liver. Som the proprietary cat foods—the better ones which are excellent—and vitamin tablets con liver, which is a rich source of the vitamin complex.

Within reason a healthy kitten should be to appetite, always provided good-quality fo are available. The amount should be restri when they are adult, however, except for pregn and lactating cats, which are sometimes referre as "queens" as opposed to the male "ton A average daily allowance of solid food f healthy non-pregnant adult cat should be of order of ¼ oz. per 1 lb. body-weight.

Cats are fastidious eaters; they usually s and examine carefully any strange or doub food. At the same time they are often gree especially with relished food to which they accustomed, but fortunately they can, like d vomit very readily. Here, incidentally, is very good tip—an excellent emetic for both and dog is a small crystal of washing-soda, gi as a pill. People are usually amazed at the this simple device results in a dog's or a cat's br ing up undesirable food.

It is important not to overfeed cats, and

most equally important to prepare all food in a an manner, and to make it as attractive as sible. Cats will greatly appreciate this care. ile milk is an excellent food for kittens (see ler breeding), and is relished by most adult s, it must be supplemented by solid food. Clean fresh water should be provided at all es, even if the cat appears to drink it but le.

BREEDING OF CATS.

Pedigree animals are normally confined, and ir breeding is strictly controlled. Ordinary sehold cats are at the opposite extreme, and re is little that can be done to prevent their ting. The length and scope of this article es not permit of a discussion of controlled thg, cientifically, there is as yet a good deal to rn about the reproductive behaviour of the . As an American physiologist has succinctly it in a description of the reproductive cycle the female cat, "no two authors agree." In rthern Europe there are two main heat periods rear, in spring and early autumn, but some rnals may appear in heat at any time from nuary to July, and those who keep female cats confinement describe their charges as "calling" te frequently if not mated. A cat which is n season" or "on heat" is often observed to behaving in a quite characteristic fashion, ling about on the floor and making peculiar nds. The periods of heat, which commence ually at about eight months of age, may last several days, and during this time the female l make every attempt to find a mate. Gestation lasts about nine weeks, as in the case the bitch, but here again there is a considerable riation. As most owners are quite unaware the time at which their cats were mated, it is ficult to talk of "going overtime," but if there any evidence of trouble during pregnancy, or birth, veterinary advice should be obtained. soon as a cat is obviously pregnant, her food owance should be increased, and she should be owed plenty of milk. It is highly important to rease her food and milk ration still further er the kittens are born, as lactation is a great in on the mother.

Cats sometimes choose strange, out-of-the-way ces in which to litter, and many healthy litters e born and reared out of doors. Rats are a rce of danger, and will often destroy very ng kittens during the mother's absence. For s and other reasons it is better in town and burban areas to have the litter comfortably sed indoors. A wooden box containing news per is ideal, provided it is kept in a fairly warm ce and out of the way of draughts. An average er consists of three to six kittens, which are rn blind, but which normally open their eyes er eight or nine days. There is no need to be rmed if the eyes remain closed for a few days ger. Kittens which are born dead should be moved and buried or burnt. If the whole er is born dead, the mother's food supply ould be cut down considerably, and little milk en for a few days. If the mamary glands come inflamed, they may be bathed in a cold ution of alum. The glands normally return their former size within a short space of time they are not milked, but if there is persistent uble veterinary advice should be sought. While many pedigree owners wean kittens at r to five weeks of age, it is strongly advised at the household cat be allowed to continue to d her family for a longer period, and eight eks is not too long if the mother is still in good dily condition. She *must*, however be well l and be allowed plenty of milk. As in the se of puppies, it is an excellent idea to provide e kittens with a little solid food as from a few eks of age. It is very wrong to remove a ten from its mother too early, and such an imal is often weakly, develops an intestinal fection, and dies as a miserable bedraggled eature. Moreover, during the period following aning the mother educates her offspring in the t of living, particularly ratting and mousing. As many litters are unwanted, some people get d of all the kittens as soon as possible after birth. rowning is frequently practised, but it is not recommended as a merciful death. Indeed, a hard blow on the back of the head is more humane if given accurately. It is much better to take the kittens to a veterinary surgeon or clinic.

DISEASES AND INJURIES OF THE CAT.

The principal infectious diseases of cats are still in need of much scientific study. It is now clear, however, that there are at least two major cat plagues. Both have been given many names, and there is much confusion between them.

Feline Enteritis or Panleucopenia.—This is a highly infectious disease, due to a filterable virus. The symptoms include loss of appetite, sometimes accompanied by a rise in body temperature, followed by listlessness, usually vomiting, sometimes diarrhoea, and a marked tendency to show tenderness or pain on being handled. This tenderness or pain is due to a developing peritonitis. The poor animal may become seriously ill, with loss of water from the tissues or dehydration, prostrate and dead within 48 hours or less from the time of the first symptoms. The incubation period of the disease is believed to be from 4 to 8 days, or sometimes longer. There is a fall in the white-cell count of the blood, hence the term "panleucopenia." Some cats recover, the recovery rate in different outbreaks that have been studied ranging from 30 to 80 per cent., and recovered animals are probably immune to further attacks. Cats that are able to take a little food during the early stages of recovery have the best chance of recovery, but require careful nursing. There may be complications during the convalescent stage due to secondary bacterial infections or to vitamin deficiency, and a light nourishing diet, combined with vitamin preparations, is recommended. Fleas may transmit the disease to other cats, as may contact with infected materials. It has been shown that bedding and dirt trays from sick cats were infectious for other cats for up to 16 days. The disease is not transmissible to dogs or to human beings. There is nowadays a protective vaccine, and it is a wise precaution to have your pet vaccinated.

Feline Pneumonitis.—This disease is sometimes called "cat distemper"—as indeed is feline enteritis—but it has no connection with dog distemper, and is not transmissible to dogs or to human beings. Both mild and severe forms occur, and the incubation period varies from 5 to 8 days. The mild form may seem like a cold, and there is a weeping from the eyes and a varying degree of conjunctivitis. There is a thin, clear discharge from the nose, with a characteristic sneezing. Provided that the animals can be made to continue eating, and are kept in warm and dry but ventilated conditions, recovery may be rapid and not entail serious loss of condition. The eyes should be treated with a suitable preparation, such as silver vitellin. There may be secondary bacterial infection in cases that are neglected.

The severe form of the disease has similar, although more severe, commencing symptoms, but the nasal discharge becomes purulent and there is often profuse salivation, with much spreading of the long ropes of saliva. The cat is listless, dislikes strong light, and seems to resent being disturbed. It loses its appetite, and rapidly becomes thinner over a period of from 2 to 5 days or so. Breathing becomes laboured, and a bronchopneumonia develops. There may be a high death rate in young kittens, and pregnant females may abort. Recovery tends to be slow, and is often complicated by bacterial infection. Some of the modern antibiotics appear to be highly effective in the treatment of many cases of this disease, but they must, of course, be given under veterinary supervision.

Tuberculosis.—The cat, like the dog, can contract tuberculosis, but so far as is known only the bovine form has been known to infect it. The infections usually comes, of course, from milk, and the elimination of bovine tuberculosis from this country will stop the incidence of the disease

in cats. The disease commences in the abdomen, but may spread to the lungs. There is general wasting.

Skin Diseases.—As in the case of the dog, skin disease in the cat is usually of parasitic origin, and fleas and mange mites are again the chief source of trouble in Great Britain. Cats do so much of their own toilet that the average household cat has probably a cleaner skin than its canine counterpart. When skin disease does develop, it is strongly advised that the animal be taken to a veterinary surgeon for appropriate treatment. As a rule cats greatly resent the interference which must accompany any attempt to bathe or dress an affected place, and for this reason it is usually unwise for an owner to attempt to do other than make an inspection. Very small patches of skin eruption may clear satisfactorily if the surrounding hair is clipped away with curved scissors, but generally speaking skin disease calls for professional attention. The cat flea has a similar life cycle to the dog flea (*see* Z8).

Diseases of the Ear.—The outer ear of the cat is frequently affected, and in a great many cases a form of mange mite is responsible. The animal provides evidence of the trouble by scratching and shaking its ear and generally showing its discomfort. It will not always be possible for an owner to make a thorough examination, as in many cases the cat objects, but if it is possible to look inside the ear it will be seen that there is a dirty and usually brownish mess of tissue, sometimes mixed with dried blood or pus. Not all cases are as bad as this, of course, but if a cat persistently worries its ear it should be taken to a veterinary surgeon. There are satisfactory dressings for this condition, and owners will be able to dress their cats if the latter are docile. Otherwise it is necessary to have the ears dressed by a veterinary surgeon or by one of his staff.

A cat's ear is frequently the site of a blood blister, or hæmatoma. This is usually the sequel to a blow, such as a slamming door, and shows itself as a large, tense swelling, which when opened by the surgeon proves to be an accumulation of serum usually tinged with blood. Some cases become infected at the time of injury, some after with the patient's rubbing. With the greatest surgical skill in the world one must expect a slight deformity, and the cat develops a puckered ear, much the same as the human boxer.

Disease of the Bladder.—The bladder is a common seat of disease in cats, and is frequently affected through the blocking of the natural water-passage by small sand-like calculi. Naturally, male cats are more often affected, as the terminal end of the urinary tracts is wider and more dilatable in females. The urine is unable to escape, and the bladder becomes filled with a mixture of urine and the sandy calcular matter. The condition may be diagnosed quite readily, as the cat usually collapses, or partially collapses, and one may easily feel the distended bladder through the walls of the abdomen (belly). It is necessary to send for professional help immediately, and, while no relief can be guaranteed, it is often possible to relieve the condition by judicious manipulation. Owners should not attempt to do this themselves (unless help cannot be obtained), as they may easily burst the bladder. As the animal is usually in a state of collapse when the condition is discovered, it makes a bad risk for actual operation, and relief by *skilled* pressure is usually to be recommended.

Ringworm.—There are two common kinds of ringworm in the cat (a third, which may also infect the dog, is more rare; it is the trichophyton which is usually found on cattle). The first kind is acquired from rats and mice, and is most commonly to be found at the bases of the claws, from where it may spread to the ears and face. The individual lesions are circular and yellow in colour, and consist largely of a scabby material. This kind of ringworm is known as "favus."

The second type of ringworm (microsporon) is more important, because it is more readily transmissible to human beings. Whereas this form usually sets up circular scaly lesions in th it often infects cats without there being naked-eye evidence of its presence. Inde the cat the condition is often unsuspected the owner himself becomes infected and co his doctor.

Ringworm should be treated or dealt w a veterinary surgeon, who will also confi refute by special methods the presence of sporon in cats.

Intestinal Parasites—"Worms."—The ca is subject to both roundworms and tapew The roundworm which parasitises cats i country is similar to that of the dog (altho different species) and is also much more ha to the young than to the adult anima kittens the symptoms are a general unthrif staring coat, and in some cases diarrhœa "pot-bellied" appearance.

The commonest cat tapeworm in this co is one which passes its intermediate stage rat or mouse, or sometimes in other ro The tapeworm, which, as mentioned und section on dogs, is dangerous to man, is times found in the cat also.

Accidents and Injuries.—Despite their sa and alertness in many ways, cats seem cu unable, in many instances, to acquire road They are dazed by a car's head-lights, whi motorist sounds his horn they tend to sto in their tracks.

Injuries from traps, *e.g.*, gin-traps, are common, and it is probable that many thou of cats annually are maimed in this fashion. suffer injury from shooting, from stoning from blows with sticks. Since they are pre animals, they have often to pay the p inflicted on them by wrathful people. No to say, cats which survive to return home u require expert treatment.

Poisoning may be included under this he Although there are doubtless many deli attempts to poison marauding cats, a "poisoning" is often no more than a c feline enteritis, and owners should not claim that their cats have been poisoned until the expert evidence to back their judgment.

Fur-balling, as it has been termed, m mentioned here. Cats, especially the long-varieties, must often ingest hair during toilet, and occasionally serious trouble (a page of the bowels) is brought about by a m such hair which has collected in a part bowel. There is constipation, loss of con and often evidence of considerable pain. cats should be taken to a veterinary surgeon

Bites and scratches are even more comm the cat than they are in the dog, and subse sepsis is equally likely.

FERRETS.

Description.—The ferret is probably a do cated form of the pole-cat (*Mustela putoriu* is known sometimes by that name and some as *Mustela furo*. Most tame ferrets have eyes and yellowish-white fur, but there are forms believed to have resulted from cross previous generations with wild pole-cats. I these darker forms are popularly termed "cat ferrets." They are of two main kind first having creamy under fur and black hairs, and the second being a chocolate-colour, with brown upper parts and black parts, and a few scattered light hairs on th

Ferrets are long creatures in relation to body weight, and when fully-grown may h body 14 in. long or more and a tail of 5 in. strains grow appreciably larger. The ma of the ferret is, of course, in rabbiting, for purpose they have been employed for centuries. Although they can become fie not accustomed to regular handling or treatment, and are capable of inflicting a bite, they may nevertheless be made into and highly intelligent pets. It is most imp to win their confidence from the beginning accustom them to regular handling from th they are young "kittens."

Accommodation.—Ferrets must have dry, clean accommodation in a room free from draughts but well ventilated. Wood is warmer than metal, but more difficult to clean, and is best lined with hard asbestos sheeting, which is resistant to water. The most suitable accommodation comprises a sleeping compartment of similar proportions to a small kennel, leading by a small doorway or "pop-hole" to a wire-netting exercising run, which should be as large as possible compatible with cleanliness. It is a good idea to have a means of closing the doorway so that the ferret or ferrets may be confined within the sleeping-compartment if necessary. Wood-wool makes an excellent bedding, but if difficult to obtain newspaper may be provided for the ferret to lie on. The floor of the run may have a false bottom or may be sprinkled with sawdust. It is important to keep the whole of the accommodation clean and dry, not only to avoid smell but also to prevent the ferrets from developing a very serious necrotic infection of the feet known as "foot-rot."

Feeding.—Many ferrets are unfortunately not fed adequately. It must be appreciated that basically they are carnivorous animals, and that their food requirements are more similar to those of the dog and cat than those of rodents. Indeed, many of the general remarks made about the principles of feeding dogs and cats apply to ferrets also.

Most ferrets like bread-and-milk, and while this is an excellent article of diet, it is in itself inadequate. Up to about 4 oz. of raw meat (minced for younger animals) daily is an excellent basis, and this may be replaced by fish. Liver, especially raw liver, is an excellent source of many factors, and there is good reason to provide some at least weekly if it can be obtained. Failing this, it is advisable to add 1–2 per cent. of whole dry liver to the diet. Once ferrets are grown, one feeding daily—at a fixed time—is sufficient. The female (jill) should have ample supplies of milk just prior to the birth of her young and while she is suckling them.

Breeding.—In the northern hemisphere the female ferret usually comes into œstrus (season) in early March of the year following that in which it is born. If the jill does not conceive during this œstrus she will have a further œstral period in July or August. The desire of the jill to mate is very strong, and if not allowed to do so, some animals sometimes have been found to waste and pine. The act of mating is prefaced by very vigorous behaviour on the part of the male (hob), and anyone not appreciating the performance might think that he was out to kill his mate! The mating act itself is usually prolonged, and may take up to three hours. If left together the hob and jill will probably mate from two to four times during the course of a couple of days. As in the cat and rabbit, ovulation or the shedding of the egg from the ovary takes place as a result of mating, and not spontaneously. The period of gestation is forty-two days, and the numbers of young born usually varies from five to thirteen, the average litter being six to eight. Pseudo-pregnancy occurs if the jill is not mated, and may become outwardly obvious as in the case of certain bitches.

Males also have a seasonal rhythm, their capacity to fertilise being greatest from early March to August. Young hobs seem to be active about a month earlier than older ones. The length of daylight or, rather, the incrementation in light from day to day, has an important bearing on breeding capacity in both sexes, and by the use of artificial light it has proved possible to induce either œstrus or male activity at different times of the year.

The young are hairless and blind, and weigh on the average under ½ oz. at birth. Their eyes open at about four weeks, and they can then commence to eat small pieces of solid food to supplement their mother's milk. They may be weaned at from six to eight weeks.

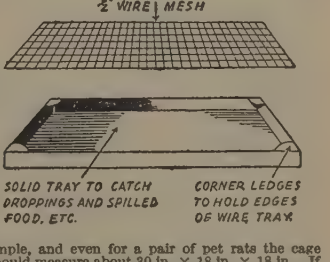
Diseases.—The most serious disease of ferrets is *canine distemper*, and the variant known as "hard pad" (see under dog) is equally capable of infecting ferrets. Such infections can wipe out entire stocks, and every care should be taken to prevent their spread from dogs to ferrets—and vice versa. A veterinary surgeon should be consulted immediately when a ferret becomes ill or out of sorts. Ferrets are also susceptible to some strains of *human* influenza, and should not be tended by persons with colds or with any indications of "flu." The feeding of infected milk may give rise to *tuberculosis* (now unlikely in Britain). *Foot-rot* has already been mentioned, and must on no account be neglected. *Mange* or "scabies" of the back and tail region should be dealt with promptly, employing modern preparations. Abscesses of the neck region are often encountered, and should receive professional treatment if they do not clear up rapidly, for they may spread with dire consequences.

RATS.

Description.—Tame rats are domesticated varieties of the wild Norway or "brown" rat (*Rattus norvegicus*). Such rats are usually albinos or black-and-white, although other colours have been bred. The hooded varieties are those in which the head and forepart are mainly black or chocolate and the remainder of the body, apart from small patches the same colours as the hood, is white. Tame rats differ materially from wild ones in disposition, and properly managed are extremely tractable. Healthy specimens accustomed to handling bite only when frightened, *e.g.*, when a sudden movement is made in front of them. Males appear to live longer than females, but three years is a good age.

"Black" rats, *i.e.*, the species (*Rattus rattus*) sometimes known as the ship or Alexandrine rat, have been bred in captivity, but tame strains are not generally available.

Housing.—Tame rats require a warm, even temperature—65–70° F. all the year round—and draughts or lowered temperature may precipitate lung disease or other disorders. It is best to have a complete spare set of boxes or cages, and to change to fresh quarters weekly except when the females have unweaned young with them. Empty cages should be cleaned and disinfected thoroughly before being used again. Provided the temperature conditions are suitable—and this is essential—metal cages of the types employed in scientific laboratories are best with wire-mesh false bottoms and trays containing sawdust to catch the droppings. Accommodation should be



ample, and even for a pair of pet rats the cage should measure about 30 in. × 18 in. × 18 in. If wooden boxes are employed it may be desirable to line them with hard asbestos sheeting or galvanised metal to prevent damage from gnawing.

Small, dark "shelters" and exercising devices, *e.g.*, wheels or ladders, are appreciated by the rats, but must be kept clean. Wood-wool makes the best bedding.

Feeding.—Rats may take a wide variety of foods, including many of our own, and there are

several successful ways of feeding them, including the provision of specially formulated "rat-cubes," of the same type as that described below for mice. A good daily diet is wholemeal bread, mixed cereals (*e.g.*, oats, wheat, hempseed), with about

WATER BULB SUITABLE FOR USE WITH PET RODENTS

5 per cent. dried brewers' yeast and milk either fed separately or mixed with the rest of the food. Twice weekly each rat should be given up to ½ oz. or more of meat, liver, fish, or other "animal protein." A little fresh greenfood (even grass) is appreciated, and in winter especially some supplement containing vitamins A and D is desirable. Expectant and nursing mothers should have as much milk as they require. Never overfeed or allow uneaten food residues to remain in the cage. Fresh water (preferably in bulbs or bottles) should be available at all times. Far cleaner than open dishes are the special but simple type of water bulbs suspended on or in front of the cage or box so that the rat can drink from the rounded end of the spout. A simple substitute is a medicine "flat" bottle—or even a ¼- or ½-pint milk-type bottle. This should be fitted with a cork—or, better, a rubber bung—pierced for a piece of bent glass tubing. Provided that the free end of the glass tubing is not sharp, and is chosen so that the aperture is considerably smaller than that of the tube itself, the water will not run out unless sucked out by the rat. The spout should, of course, be within easy access of the rat, which will soon learn to drink from it.

Breeding.—Rats can breed at quite a young age (usually being capable of mating when fifty to sixty days old), but it is better to separate the sexes within a fortnight or so of weaning (weaning being usually at twenty-one days of age) and to mate at about 100 to 120 days of age onwards. the female rat has an œstrous cycle lasting just over four days. One male (buck) may be mated to one female (doe)—this is probably best in the case of pet rats—or with two or three females if preferred, but it is unwise to keep more than one adult male in the presence of females. The gestation period is twenty-one to twenty-two days or occasionally a few days longer. The number born varies considerably, but often it is best to try to rear only six to eight young. The young have their ears open at 2½ to 3½ days, cut their incisor teeth at eight to ten days, can find their way to their mother at about the same time, open their eyes at fourteen to seventeen days, and may leave the nest at twenty-one days. In the case of pet rats it is probably best to leave the young with the mother for up to a week or so longer. Breeding can occur all the year round, but takes place less readily in winter.

Handling.—Rats should not be "tailed," or the skin may slough off. Regular handling after weaning is excellent and promotes docility. The weight of the body should be supported.

Diseases.—On the whole rats are much less liable to disease than mice, provided temperature conditions are suitable. The commonest infection is *broncho-pneumonia*, often precipitated through draughts or cold. *Mange* (especially of the e and infestation with *lice* may occur, and sho be dealt with promptly by means of mod insecticides. Avoid contact with wild rodents, the use of food or bedding that may have be contaminated by wild rats and mice.

MICE.

Description.—Tame mice are descended fr the common house mouse (*Mus musculus*), and is believed that mice have been domesticated over 3,000 years. Apart from albino or "wh mice," there are many varieties that have be bred by the extensive "mouse fancy," and th is a wide range of coat colour and also differ types of coat, *e.g.*, long-haired, short-haired, a rex. "Waltzing mice" have an abnormality that part of the inner ear concerned with balan Mice may live up to thirty months, and in exc tional cases attain the age of three years more.

Housing.—Although strains vary, most ta mice require a warm even temperature and same general remarks concerning temperat range, bedding, and wooden or metal cages ap as in the case of rats. If a solid floor is us this should be covered with clean sawdust. is a good plan to change to a clean cage regular except when the female (doe) is nursing her you If the cage is large (as in the case of pet mice should be, with a floor space of say 24 in. 12 in. × 12 in. for a group of mice), inner ne boxes should be provided—one for each doe breeding is taking place, although two does w often share the same nest-box. (In changing fresh cages the nest-box, with mother and you inside, may, of course, be moved over.) A "t storey" cage, with a ladder or "staircase" the upper part, is an attractive variation, althou difficult to keep clean. Mice should be kept w out of reach of wild rodents, from which they m all too readily contract disease.

Feeding.—Mice have not quite such a w dietary range as rats, but there are several diff ent ways of feeding them, including the provis of special "mouse cubes." These mouse cu are of varying composition. One of the m successful, devised by workers in the Medi Research Council's laboratories, is known "Diet 41," and is made up of the following pa by weight: wholemeal flour, 45; Sussex grou oats, 40; fish meal, 8; dried yeast, 1; dr skimmed milk, 3; cod-liver oil, 1; and comm salt, 1. Diet 41 has also been employed for r and monkeys, although for the latter particula it requires supplementing. It is perhaps wo emphasising that cod-liver oil must not be in excess (½% of the diet is quite sufficient, should not be exceeded), or it may prev breeding and possibly have other harmful effe Cubed diets are best fed from a wire bas through which the mice enjoy gnawing eventually pulling out the pieces. Wholem bread is excellent if not allowed to become st but it should not form the sole article of diet, it is a good idea to feed it alternately with a gr mixture (made up of rolled oats, wheat and ot cereal grains, or mixed bird seed). Up to ab 5 per cent. dried brewers' yeast is excellent, so is fresh or dried milk, especially for moth that are carrying or nursing young. Cheese relished, but may smell if not fed carefu Mice sometimes like an occasional pinch of marm lade, and it is a good idea to provide lettuce other greenfood every week or so. There sho be a constant supply of fresh water, prefera from bulbs or bottles as described for rats.

Breeding.—Young mice may be weaned twenty-one days, although it is usually prefers to leave them with their mother for a furt week. The age at which mice are capable mating varies considerably from one strain individual to another, and while the average six to eight weeks, it may be much youn It is therefore desirable to separate the m from the females at or shortly after weani

lice may be mated up at two to three months of
re, and the best arrangements are one male
ouch) to one or two females. A pair of mice or
" bigmouse trio " makes a successful combina-
on. The œstrus cycle is similar to that of the
t, but its length appears to vary with coat
olour, being longest in the brown mice and
ortest in blacks and albinos. The gestation
eriod is usually from eighteen to twenty days,
it may be prolonged if the female was still
uckling her previous litter when she conceived.
here may be up to twelve or more young in a
tter, but the average litter size is from five to
ven. The second litter is usually the largest,
nd subsequent litters tend to decrease in num-
ers, so that the sixth is usually smaller than the
st. Breeding may take place all the year round,
though, as with rats, fertility is higher during
he summer months.

Handling.—Any rapid or rough movement may
ighten mice and cause them to bite through fear.
ice should be lifted by the tail—not too near the
p—and may be held in the palm of the hand,
here they may be suitably restrained by keeping
he tail between two fingers.

Diseases.—Mice are unfortunately prone to
any diseases, although the risks will be much
wer if they are kept in suitable surroundings,
reat care is taken to avoid infection, scrupulous
eanliness is observed, and the standard of feed-
g is good. One common source of infection is
e presence of the excreta of wild rodents on
edding or foodstuffs. A common disease is that
metimes called "*mouse typhoid*," caused by
ganisms of the Salmonella group. Although
me mice recover, they may remain carriers of
fection, and once this disease is diagnosed it is
st to destroy the affected mice and those in
ntact with them, and not to employ any of the
ages or utensils for the mice without adequate
erilisation. There are other septicæmia diseases
mice, and also virus diseases, including certain
pes of *pneumonia* and a condition known as
fectious ectromelia. The accurate diagnosis of
ese calls for expert opinion and often for special
acteriological or other examinations. The
ouse-owner should, however, be able to recognise
gns of ill-health or departure from normal, one
the commonest being loss of appetite. In
oung mice the coat should be smooth and glossy.
s mice get older there may be loss of pigmenta-
on (in coloured mice) or even loss of fur. A sick
ouse usually sits hunched up and has a ruffled
at, while the eyes may be partially closed or
ave some discharge. A healthy mouse will
sually catch on to suitable objects when held by
s tail and is capable of pulling quite hard,
hereas the pull of a sick mouse is much weaker.
one or more mice die it is best to destroy at
nce any cage-mates that appear seedy. As in
e case of rats, external parasites should be dealt
ith promptly with the aid of modern insecticidal
reparations.

GOLDEN HAMSTERS.

Description.—There are many species of ham-
ers in the world, and more than one kind can
ow be bred in captivity. The one referred to,
owever, is the Golden Hamster (*Mesocricetus
uratus*), a delightful little creature of which a full-
own female (females are larger than males)
rely exceeds 7 in. in length. This history of the
omestication of the golden hamster is quite
markable, for prior to 1930 only museum speci-
ens were known. In that year a mother and
r twelve young were dug up in a field near
leppo and were taken to the Hebrew University,
erusalem, and from that one family have been
ed the hundreds of thousands of golden hamsters
ow employed as pets or as laboratory animals in
any parts of the world. The species has taken
ell to captivity and, although capable of inflict-
g a nasty little bite if frightened or handled
ughly, becomes docile and friendly when pro-
erly cared for. Characteristic features are the
ft, smooth fur, the large black eyes, the " cheek
pouches " in which food is stored and which may
become enormously distended after a meal, the
short, stumpy tail, and the extremely loose skin,
inside which the hamster can turn round to a
considerable degree.

Housing.—The same remarks about accom-
modation, environmental temperature, freedom
from draughts, fittings, and other general con-
siderations (including cleanliness) apply as in the
case of rats and mice. For breeding purposes a
dark inner chamber or nest-box is desirable.
Several hamsters may be kept together, but the
introduction of a stranger (or even the re-intro-
duction of a former cage-mate that has been
removed for some time) may lead to fighting.

Feeding.—Satisfactory diets include the follow-
ing: (1) rat cubes (*e.g.*, " Diet 41 "), carrots,
greenfood, and milk; (2) cereal grains and/or
wholemeal bread, carrots, greenfood, and milk;
(3) steamed Rangoon beans, wheat, maize meal
bread, a little Marmite, and milk. Care must be
taken not to allow storage of excess food, which
will deteriorate and cause a smell. Grass is a
suitable source of greenfood during its growing
season. Apples and other fruits are often re-
lished. Water, preferably in bulbs or bottles as
described for rats, should always be available.

Breeding.—Golden Hamsters attain puberty at
from ten to fifteen weeks of age, or even younger,
males being usually earlier. Generally speaking,
it is best to defer breeding until after fifteen weeks
of age. There is an œstrus cycle of about four
days, and the gestation period is very short,
averaging sixteen days, although sometimes up
to nineteen days. Mating not followed by con-
ception results in phantom or pseudopregnancy.
Litter size varies from one to fifteen, but the
average is six to seven. Not many females have
more than four litters and although both sexes
may live up to two years, breeding by the female
is rare after nine months. The young are naked
and blind at birth. Hair first appears at five
days, and covers the whole body at eight days.
The eyes open at about eleven days, and soon after
this the young begin to take food for themselves
and may be weaned at three to four weeks. Care
must be taken that the female does not injure the
male, and for safety's sake it is probably better to
keep only one female and one male together and
to remove the male before the young are born.

Handling.—Gentleness is essential, and sudden
movements should be avoided. The tail is much
too short to use, and the easiest way is to lift
them by the loose skin over the back and shoul-
ders. As already noted, they can twist easily
within their skins, unless a substantial amount is
taken in the hand. After picking up they may
be allowed to sit on the palm of the hand.

Diseases.—Several diseases of hamsters are
now known, and, like most rodents, they are
susceptible to *Salmonellosis* (see notes under
" mouse typhoid " and " paratyphoid " in
guinea-pigs). One of the most prevalent condi-
tions is *ear mange*, in severe cases of which the
condition spreads from the ears to other parts of
the body. Modern anti-mange preparations are
highly effective.

CAVIES (GUINEA-PIGS).

Description.—Cavies or guinea-pigs (*Cavia
porcellus*) are rodents, and are descended from one
or more of the several kinds of wild cavy found
in South America. They are believed to have
been domesticated by the Incas long before
Europeans " discovered " that part of the world.
They make excellent pets, but are easily fright-
ened, and should be treated gently and quietly.
They usually behave quietly, although there may
be fighting between adult males (" boars "), while
the arrival of food—or the entry of a person into
a room, which fact is obviously connected with
feeding-time—usually sets up a chorus of chirrup-

ing squeaks. There is to-day a considerable cavy "fancy" in Great Britain and other countries, and many varieties are recognised, including rough-coated and smooth-coated types. Among recognised colours are the agouti (banded hairs), brindle, cinnamon, tortoiseshell (tricoloured), and Himalayan (white with attractive black points). The long-haired Peruvian and rosette-haired Abyssinian breeds are popular. Guinea-pigs may live up to two to three years. There is a small tail (composed of from five to seven caudal vertebræ), but usually this is so short that it does not project outside the body. There are four toes on each of the fore-feet and three on each hind foot. An adult guinea-pig may measure up to 10 in. or more in length, and sometimes its weight is well over 2 lb.

Housing.—Guinea-pigs may be kept outside or inside. If outside conditions are favoured, great care must be taken to protect them from dogs, cats, and rats. The last-named may be a danger also in conveying disease. The run should be in a sheltered position away from wind and direct summer sunlight. Tent-shaped waterproof shelters, with wooden floors covered by cleaning trays, have been found satisfactory. Another method is to keep them in hutches of the same type employed for rabbits and when conditions are suitable to let them out into a temporary run on the lawn surrounded by ½ in.-mesh wire-netting that is at least 12 in. high. (N.B. This will keep dogs or cats out.) Guinea-pigs will crop the grass and help to keep the lawn smooth. Great care should be taken not to allow the ground or floor to become so contaminated by guinea-pig excreta that it conveys disease from one animal to another.

If indoor methods are selected, an even, preferably warm temperature is desirable, and there should be freedom from draughts. Guinea-pigs have been found to thrive best at about 65° F. with a humidity range of 45–55 per cent. Provided warm conditions are available, metal cages are easier to keep clean than wooden ones, while a false bottom of wire mesh, above the cleaning tray, is helpful. Wood-wool is again the best bedding. Cages must not be too small, and a pair of pet guinea-pigs should have about 14 sq. ft. of floor space. It is a sound principle, as with rats and mice, to change frequently to a clean cage, the used one being cleaned and disinfected thoroughly before being used again.

Feeding.—Guinea-pigs, like human beings, apes, and monkeys, require a source of vitamin C (ascorbic acid). Normally they obtain this from greenfood, but in winter especially they may not secure enough in this way. The daily requirement of an adult guinea-pig is about 2 milligrammes, and supplies can be obtained from a chemist's shop.

There are many different methods of feeding guinea-pigs. Among cubed or pelleted diets is that known as "Diet 18," which is employed also for rabbits. It contains the following parts by weight: wheat feed, 15; grass meal, 80; decorticated groundnut meal, 15; linseed cake, 10; barley meal, 20; common salt, 1; and chalk, 1. This is fed together with fresh greenfood to supply vitamin C. For feeding without the use of compressed diets a good plan is to provide a daily "concentrate ration" of about 1 oz. per head of a mixture of 2 parts bran and 1 part crushed oats, and to feed in addition ample amounts of cabbage, lettuce or other greenfood, meadow hay of good quality, grass, and raw vegetables. Although guinea-pigs normally derive moisture from fresh greenfood, and may appear to take little or no water for long periods, it is a mistake not to provide a fresh supply, preferably from water bulbs, or from inverted bottles fitted with a stopper and drinking-spout. A little dried brewers' yeast makes an excellent addition to the diet, while for females ("sows") when pregnant or lactating, milk is excellent. Dead foliage should be removed from greenfood, and soil and dirt cleaned off. Frosted greenfood should be soaked in warm water before it is given to guinea-pigs. Unfortunately, hay may be contaminated by wild rodents, but it forms an excellent article of diet. Never allow food dues to remain in the cage.

Breeding.—The lactation period of the gui pig is a short one. The gestation period aver sixty-three to seventy-five days, although va tions of fifty-eight to seventy-two days are kn and the young are born in an advanced st with their eyes already open. They can freely with their mother shortly after birth. T are able to nibble a little food as early as second day, and by the time they are two to t weeks old they are completely independent are neglected by their mother. A sow will c mate again the day the young are born, or shc after, so that a rapid succession of litters c occurs.

Guinea-pigs are capable of mating from al fifty-five days of age, or even younger in cer circumstances, which include the provision high plane of nutrition. The œstrous c averages fifteen to seventeen days, although it vary from thirteen to twenty-five days. actual period during which mating may o usually lasts only from about six to eleven hc One boar may run with as many as twenty s if so desired, but in the case of pets it is n more interesting to run a boar with only one in which case she need not usually be remove a separate cage before the young are born. young guinea-pigs should be separated from older ones shortly after weaning, and the s separated at four to five weeks of age if they not to breed prematurely. It is better to until the animals are approaching six month age or so before they are mated, for they do become fully grown and "filled out" until t are between six and nine months.

Handling.—Guinea-pigs are timid creatu and should be handled gently. They are picked up with both hands. If a guinea-pi to be held in order to examine it for any purp a good method is to place one hand over animal's shoulders, with the fingers and th around its neck, and to extend its hind limbs with the other hand.

Diseases.—The most important infect disease of guinea-pigs is, like "mouse typho caused by organisms of the Salmonella group, it may be contracted from wild rodents or f food or bedding contaminated by them. guinea-pigs the disease is known usually "*paratyphoid*" (or sometimes as "*salmonellos* and it may take an acute form, causing d within a few days, or a more chronic form which many animals recover to become sympt less carriers of disease. Outwardly healthy, t may infect susceptible guinea-pigs with w they are placed. Cold or other environme variations, and faulty feeding, can help to se an outbreak, for there are few stocks in which organisms are not lurking in some "la carriers." *Coccidiosis* is common, but is a m less serious threat than in the case of rab It has been set up in infected stocks by fee inadequate diets, and provided that nutri and hygiene are adequate there is rarely ser trouble from this disease. *Infections of respiratory tract* may occur, but are uncom except when there is overcrowding, high humi or damp bedding. Sometimes organisms of Pneumococcus group cause not only disease of respiratory tract but also a generalised infec of the serous membranes of the body. When disease occurs it may produce death without m warning. It is possible that the infection sc times comes from human beings. The dis known as *pseudotuberculosis*, and described u rabbits, occurs in guinea-pigs also. A environmental conditions and faulty feeding predispose towards active infection.

With good fortune and sound managem trouble from these serious infections may n occur. *External parasites* should be dealt promptly by insecticides. Sometimes *parasitic skin disorders* occur when the die faulty, *e.g.*, too dry or lacking in sufficient f greenfood of good quality.

RABBITS.

Description.—Domesticated varieties of the wild European rabbit (*Oryctolagus cuniculus*) are now kept in many countries. The wild rabbit is believed to have been introduced into Great Britain in the 12th cent. Tame rabbits have been bred for centuries, and the breeds and strains produced differ appreciably in size, colour, and habits from the common wild form. Some breeds have been specially bred for table purposes, while others (*e.g.*, the Angora, Sitka, and Argente de Champagne) have been developed for their fur. In addition, many varieties are produced for show purposes by the extensive rabbit "fancy." The small hardy Dutch rabbit (usually black and white) is one of the kinds suitable for beginners. Among well-known categories are the English, Japanese, Himalayan, Belgian Hare (really a rabbit), Flemish Giant, Beveren, Blue Imperial, Polish, Havana, Lop, Half-Lop, Chinchilla, and New Zealand White. The Copenhagen rabbit appears to be identical with the New Zealand White. The smaller breeds weigh only 4–6 lb. when fully grown, whereas some specimens of some of the giant breeds attain a weight of 20 lb. or more.

Rabbits and hares were formerly classified with the rodents, but are now placed in a separate Order of mammals, known as the Lagomorphs. Young rabbits (in contrast to leverets or young hares) are blind and helpless for some time after birth. Tame specimens may live for 4–5 years, and individuals have lived for up to 13 years.

Housing.—Since rabbits are kept for commercial purposes, various systems have been devised, including the use of movable ark-huts, with covered runs, that can be moved regularly to fresh ground. If kept indoors rabbits do not need special heating, but freedom from draughts, damp, excessive cold, and access by wild rodents is most desirable. A garage is regarded as an unsuitable place, owing to the susceptibility of rabbits to exhaust or engine fumes. One of the great difficulties of rabbit-keeping is coccidiosis, which is a serious disease in rabbits and hares. (European hares could never be bred successfully in captivity until means of overcoming coccidiosis were discovered.) With young rabbits especially (*i.e.*, those that have left the nest and are able to run about freely) it is a sound principle to move them to a clean floor or fresh ground every two days, so as to "break" the life-cycle of the coccidial parasite. One way of doing this is to have "back-to-back" cages or hutches, from one to the other of which the rabbit may be transferred easily. The empty cage or hutch may then be cleaned and disinfected thoroughly and allowed to dry out before the rabbits are returned to it. Wood-wool makes a suitable bedding material, although the female (doe) will pluck her own fur to line the nest when her litter is due to be born. Wire-mesh floors with a tray beneath are convenient, but if solid floors are used these should be sprinkled with fresh sawdust daily or every other day. Provided the standard of hygiene can be maintained, cages or hutches and their runs should be large. The absolute minimum is 4 sq. ft. of floor space for each lb. weight of adult rabbit," *i.e.*, if there are two rabbits totalling 12 lb. in weight there must be at least 12 sq. ft. of floor space. If cages or hutches are stacked one on top of the other the lowest should be well clear of the ground, and if there is only one hutch this, for convenience and safety from wild rodents, should be 2–3 ft. off the floor.

Feeding.—The wild rabbit grazes at dusk and dawn, and it is preferable to feed tame rabbits twice daily, while pregnant or lactating does and young rabbits benefit from three meals a day. As in the case of guinea-pigs, the ration may be thought of as consisting of two parts, a concentrate portion and a portion consisting of greenfood and other succulent material. The concentrate portion consists usually of a mixture of cereal grains or of some other form of mash. Successful mashes, of which there are many, include: (1) a mixture of 4 parts cereal grains and 1 part dairy cake; (2) equal parts of bran, weatings, fish and maize—or barley meal—and fish meal. This second is useful for breeding. If materials for the mash are in short supply they may in part be replaced by cooked potatoes. An average daily food allowance for a resting (non-breeding) adult of medium size would be: greenfood (grass, clover, weeds, lettuce, etc.) and/or roots, 12–16 oz.; hay (good quality), 2–3 oz.; and concentrates (cereal grain or meal mash), 2 oz. If cooked potatoes are used they should be fed at the rate of 4 parts to each 1 part of cereal that they replace. For a doe nursing her litter a suitable diet would comprise: greenfood to appetite, hay (good quality and preferably containing clover or other legume), 2–4 oz.; concentrates (preferably with fish meal or some other suitable source of "animal protein"), 4–6 oz.; and common salt at the level of up to 1 per cent. of the ration. A mineral mixture is preferable to salt alone. Excessive greenfood, especially in the form of cabbage and other Brassica plants, may cause polyuria, *i.e.*, the passage of excessive quantities of urine. No matter how much fresh greenfood rabbits may have available, a supply of fresh water should always be provided. The daily water requirement of the rabbit is quite high, and certain bad habits such as urine drinking or even cannibalism may result from an inadequate intake of water. Pots that cannot be overturned or, preferably, water bulbs or bottles as described for guinea-pigs, are the most suitable means of providing water.

"Diet 18," described under guinea-pigs, is one of several types of compressed diet successfully employed for rabbits. Fresh greenfood is preferably fed in addition, while the water requirement with diets of this kind is considerable.

Breeding.—The age of puberty varies with the breed, and also with the time of year at which the individual rabbit was born. Rabbits born in spring are usually capable of breeding at a younger age than those born in the autumn. In Great Britain the wild rabbit has a fairly sharply defined main breeding season, lasting from January to June, but some degree of "out-of-season" breeding may take place at almost all other times. Tame rabbits may not breed freely during the winter months, especially if environmental conditions are cold. Mating may take place as early as four months of age, and although this does not often result in pregnancy, it is accompanied by competition and fighting between individuals of the same sex. Males (bucks) and females should therefore be separated at weaning or at least before they are four months old. Fertile matings may occur at from about 5½ months of age onwards, but it is wise to defer breeding until later—say seven to eight months for most breeds. The female does not ovulate or shed her eggs from the ovary spontaneously as do most domestic mammals, but, like the cat and ferret, does so in response to the act of mating or some other strong stimulus. Even playing between two does may precipitate ovulation, in which case a so-called "phantom pregnancy" (pseudopregnancy) may result, the doe that has ovulated appearing pregnant and even developing lactating mammary glands. There is not therefore an obvious regularly recurring œstrus cycle as in the domestic rat, mouse, and guinea-pig, and in summer at least the doe may be ready to mate at almost any time. Observation suggests, however, that there are fluctuations in the desire to mate. The act of mating in rabbits sometimes causes alarm that all is not well to those that have not hitherto witnessed it, for the buck usually emits a peculiar cry and loses his balance to fall over sideways. It is usually best to separate the buck from the doe before the young are born. The gestation period is usually thirty to thirty-two days. In wild rabbits a high percentage of embryos die and are "resorbed," and are therefore never born. In some populations it appears that about two-thirds of all rabbits conceived (including about 60 per cent. of total litters) are lost before birth in this way. Losses from this cause are probably much less common in domesticated rabbits, especially when the standards of feeding and management are high. Litter size is variable, and depends in part on the breed or strain. In some strains mean litter sizes up to eight or nine have been obtained, but a mean of four or so is more common. Does that do not prepare the nest or

rear their young properly should not be selected for further breeding. The doe with her new-born litter should not be disturbed unduly, or she may desert her young, which are blind and helpless at birth and are entirely dependent on her for at least three weeks, after which they begin to nibble food to supplement the milk that they receive from her. The eyes open at about fourteen days. Weaning should be carried out at between six and eight weeks of age, by which time the young should be able to fend for themselves completely.

Handling.—Rabbits should never be lifted by the ears alone. One good way of lifting them is to grip the ears firmly but gently with one hand and to place the other hand under the rump to take the weight of the rabbit's body. Alternatively, one hand may be placed flat under the rabbit's belly, but this requires more care, and may be a risky procedure with pregnant does. Another convenient way to handle rabbits, especially young ones, is to lift them by the loose skin over the shoulders. Rabbits can inflict quite nasty scratches with the nails of the hind feet. It is incidentally a good plan to examine the nails of all four feet and to trim them if they are too long. A stout pair of scissors, or preferably a pair of clippers, is used, and care should be taken not to cut back as far as the "quick," *i.e.*, the bluish portion at the base of the nail that contains blood vessels and will bleed freely if damaged.

Diseases.—As already indicated, *coccidiosis* is a highly important disease of young rabbits. It may be either of the "hepatic type," affecting principally the liver, or the "intestinal type," affecting principally the gut. Even in the case of the hepatic type, however, the coccidial parasites are picked up by mouth and after penetrating the intestinal walls make their way via the blood-stream to the liver. Hygienic measures are the best means of preventing the disease (see under Housing), but should it break out, prompt treatment with certain sulphonamides or other anti-coccidial drugs may prove effective. In certain rabbitries in which coccidiosis is a constant problem, protection has been obtained by feeding a dilute solution of one of the soluble sulphonamides in place of drinking-water. There are certain types of digestive disturbance that may resemble coccidiosis, and one of these, the cause of which has not yet been established with certainty, is known as *mucoid enteritis*. Some such cases are probably variations of "*bloat*" ("the blows") a condition the cause of which is again not fully established, although there may in fact be several factors. A rabbit may, of course, "blow" after eating fermentative food, but cases of "bloat" can occur independently of this, and some may be due to a virus. "*Snuffles*" is characterised by a nasal discharge, and is not always associated with the same organism. In its milder forms it is not a severe disease, but with the more chronic forms the nasal discharge becomes marked and gives rise to a typical sniffling noise. Severe chronic cases become progressively worse and die of a terminal pneumonia. There is also a severe acute form, in which the rabbit dies so rapidly that the condition is sometimes not recognised. Acute cases that are treated in time with certain sulphonamides may respond well, but chronic snufflers are difficult to treat and go on spreading the infection, and hence are better destroyed. Correct environmental conditions are a great help in preventing this disease. A chronic type of infection is known as *pseudotuberculosis*, which is usually acquired from eating material contaminated by wild rodents or by other infected rabbits. It is caused by quite a different organism from that of true tuberculosis, which is much rarer in rabbits. Clinical cases should be killed, and prevention lies in hygienic measures. Infected wounds or skin abscesses may lead to a disease caused by the "necrosis bacillus" (*Fusiformis necrophorus*) and known sometimes as *necrobacillosis* It is usually characterised by subcutaneous swellings distributed irregularly over the head and body. Although in the early stages the affected rabbit may remain in apparently good health, the spread of the disease is insidious and usually fatal, and in most instances it is kinder and safer to destroy a case before it progresses too far. There are unfortunately several other infectious conditions occurring in rabbits, but all call for expert help in diagnosis and treatment. Generally speaking, it is a policy not to cull an ailing rabbit immediately, and one that is ill should certainly be isolated at once and not fed or tended before the pen is looking after it touches the healthy rabbits.

Among non-infectious conditions *pregnancy toxæmia* is not uncommon in does during the whole late pregnancy, and usually proves fatal within two to three days. It is a "metabolic disorder," *i.e.*, it is associated with some functional derangement of the endocrine or ductless glands or with the inability to control properly the utilisation of its food. Faulty feeding is probably a contributory cause. Diseases of the *heart* and *blood* may arise occasionally, and can be aggravated by faulty feeding.

Among external parasites, *ringworm* is common, but may be acquired from rodents. Affected rabbits that are to be treated must be isolated. *Ear mange* (known usually as *canker*) is common, and may be treated by the attention to hygiene, with thorough disinfection of the hut or cage, and by dressing with a mod anti-mange preparation. *Body mange* is much common but far more difficult to treat.

Among internal parasites, so-called "*blood worms*," *i.e.*, the larval stages of two dog tape worms (*Taenia pisiformis* and *Taenia serialis*) quite common, although rarely fatal. The feeding of grass or other greenstuff to which dogs have had access should be avoided, as well as contamination of the drinking-water with faeces.

Domestic rabbits are susceptible to myxomatosis, and it is a wise precaution to have them vaccinated. The vaccine is inexpensive, and may be obtained through veterinary surgeons or pharmacists.

HEDGEHOGS.

Description.—The European hedgehog (*Erinaceus europaeus*), found throughout Great Britain belongs to the Order Insectivora, of which moles and shrews are also members. Its diet is, however, by no means restricted to insects, although in nature a considerable portion is probably made up of small invertebrates. There is a great deal of prejudice against them as pets, owing to the fact that freshly caught specimens are usually infested with fleas or other external parasites. The spines of the hedgehog, being well-spaced, make the presence of external parasites more obvious than is the case in animals with a coat of close fur. The hedgehog's spines form its defence, and its capacity to roll up into a prickly ball at the threat of danger is well known. This defensive reaction is unfortunately of no avail to it when the danger is an oncoming car or lorry. Thousands of hedgehogs die every years as a result of being killed by vehicles on the roads. Most other species of mammals wander on to the road, but most attempt to flee when they sense the approach of a vehicle. The capacity to roll up is not secure defence even against animal enemies. There are some foxes, dogs, and cats that have learned to "uncurl" a hedgehog, and subsequently eat it.

Provided that care is taken, a hedgehog makes an excellent pet, especially if given a suitable enclosure in the garden. For a variable time during winter hedgehogs hibernate, and during this time they must not be disturbed. Should they emerge at any time however, food must be provided. Some specimens have lived for years or more in captivity.

Accommodation.—The most satisfactory way to maintain a pet hedgehog is to provide it with a large "run" in part of the garden. If wire netting is employed it should be sunk under the ground to a depth of several inches, or the hedgehog will burrow underneath and escape. The top of the run must be wired in, or alternati

ere must be a " baffle board " or wire-frame (at ast 9 in. wide) near the tope of the sides to event escape that way, for hedgehogs can scale re-netting—and some other types of fence—th ease. There should be a warm, dry box for elter, containing wood-wool or other bedding aterial. A simple but suitable shelter may be ade out of a soap-box, preferably lined with bestos sheeting or some other material imper- ous to water. A shallow sunken bath in the closure may be of interest for hedgehogs take ll to water, but the edges should be such that e hedgehog can get out easily.

If it is decided to keep a hedgehog indoors, then e best accommodation is probably similar to at described for ferrets.

Feeding.—The simplest diet consists of milk, me bread, and minced lean meat. Cooked meat preferred to raw, but raw liver should be given casionally. Another satisfactory diet comprises eat offals, " root " vegetables (*e.g.*, carrot, tato, and swede), and wheaten wholemeal scuit, steamed together until cooked, and then ixed and minced with a small proportion of raw er. A small quantity (say 1–2 per cent.) of ineral mixture is also desirable, and milk should given freely. Although hedgehogs appear to ink but little water, a fresh supply should always provided

Breeding.—During the breeding season marked anges occur in both males and females, and the ructures associated with reproduction increase ormously in size from about March onwards. he female is capable of having two litters a year, e first in May or June and the second in August September. The period of gestation has not en determined exactly, but is believed to be irty-five days, possibly with variations of up to ll over forty days. During the breeding season e males are very pugnacious towards each other females are with them, and may do each other nsiderable damage. (The mixing of strange dgehogs is often a difficult procedure anyway, r they often fight and inflict nasty bites on one nother's feet.)

The litter size is usually four to six, and the oung, which have " soft " spines, are suckled r their mother for nearly six weeks. The young n partake of some solid food at about three eeks, and there is some evidence that if left with eir mother for longer than six weeks she may mpete unfairly with them for food!

Diseases.—Hedgehogs in captivity are susceptible to *respiratory infections*, and can sometimes ntract certain strains of *human influenza*. hey are susceptible also to *Salmonellosis* (see der mice and guinea-pigs). Fleas and other ternal parasites have been mentioned; these ten disappear spontaneously as the hedgehog gins to thrive in captivity, but if not they should e dealt with by modern methods. The nails of a dgehog may need trimming. (*See* Rabbits.)

LAND TORTOISES.

Tortoises are popular pets, but although many e kept with great success in Great Britain, the ajority of those that are imported each year are ver looked after adequately, or fail to thrive r other reasons.

Most land tortoises that are imported into Great ritain for sale through dealers are: (1) the our-thighed Mediterranean Land Tortoise *estudo graeca*), commonly known as the " Moroc- n tortoise " and sometimes as the " Tberian " " Algerian "; or (2) Hermann's Tortoise *estudo hermanni*). The second is distributed in outhern France, Southern Italy, the larger islands the Western Mediterranean, and parts of ugoslavia, Albania, and Greece. There is a pecies found in Greece, the Margined Tortoise *estudo marginata*), but while adaptable to life Great Britain, it is more difficult to acquire. he two common species differ in several ways. e " Moroccan tortoise " having a small bony ur on the back of the thigh. (The upper part the shell is termed the carapace and the ventral ortion the plastron.)

In selecting a tortoise one should ensure that the animal appears healthy. It should be active and withdraw quickly into its shell on being disturbed. Its legs should be firm and not limp, and there should be no abnormal discharge from the eyes or nostrils. The shell and limbs should be uninjured. Females are generally larger and have a shorter tail than the male. The shield above the tail is flat in the former and curved in the male. It is a good idea to obtain a pair or more of tortoises, but not more than can be looked after with care. On being purchased they should be washed in tepid water.

Many tortoises are given free range in gardens, but this is not advised with all, as they eat a wide variety of vegetables and young plants, and being wandering animals are liable to get lost if the garden is not completely fenced or walled. They should be provided with as large a " pen " or " run " as possible, the walls or wire netting of which should be high enough to prevent their climbing over. The practice of tethering tortoises by a hole in the shell should be discouraged. They should always be provided with a box or shelter, the cheapest form being a wooden soap box turned on one side and with a sufficiently wide entrance, the wood being creosoted and covered with roofing felt. It can be lined with asbestos sheeting if desired, and have its floor covered with dry leaves or other bedding material. Some other shelter should also be provided in the run. The tortoises should be bathed during the hot weather. The occasional application of olive oil will keep the shell polished.

Land tortoises must be fed daily, and it is important to allow them to build up good reserves to enable them to hibernate through the winter successfully. Suitable foods include lettuce, young cabbage, peas, clover, dandelions, and a wide variety of green plants and ripe, sweet fruits. Generally bread and milk should be avoided. For young tortoises especially, it is recommended that once weekly or so the food should be sprinkled with powdered cuttlefish bone, or better still a small quantity of powered calcium gluconate or cod-liver oil. Fresh water in a shallow tray, or even a saucer, should always be provided.

One of the most difficult problems in tortoise keeping is hibernation. Some persons avoid allowing their pets to hibernate by transferring them to a warm place, such as a heated greenhouse; if this is done they must be kept well fed and their place maintained at a summer temperature. It is imperative to do one thing or the other—the half-torpid tortoise that is neither hibernating nor kept at summer temperature will die. Moreover, a tortoise that is allowed to hibernate must not be disturbed.

Signs of pending hibernation, including sluggishness and lowered appetite, are usually evident late in September or early in October. Tortoises living in the garden may commence to bury themselves. If this is allowed they must be well covered, else they may be killed by the ensuing frost. It is, though, more convenient and perhaps provides a greater chance of survival, due to the changeable winter conditions in Britain, to place the animal in a large box, which should be packed with straw, leaves, or hay. The box should be stored in a cool but frostproof place, such as out-building, cellar, or attic. It is important not to create conditions that will awaken the tortoise or tempt it to emerge before the following spring. Rats have been known to attack hibernating tortoises, and so due precautions should be taken.

On emerging from hibernation the eyes and nostrils are somewhat sealed, and should be released by bathing with a 4 per cent. boric acid solution and warm water.

Recently imported female tortoises frequently lay eggs, but it is not a common occurrence for pairs to breed freely in Britain. During the early part of the summer the male is sometimes seen butting the shell of the female, this being a courtship action. If eggs are laid it is unlikely that they will be fertile, and less likely that they can be hatched. They have been hatched by placing them on damp sand and storing them in a warm place—a heated greenhouse or airing cupboard. The eggs should not be disturbed or " turned " once incubation has commenced.

Tortoise ticks are often present on freshly imported specimens, and may best be removed by

damping the tick with paraffin or methylated spirits and then removing it gently with tweezers. Round worms are very numerous in tortoises, and should they be seen in the faecal matter the remainder may be eliminated by sprinkling up to one grain of powdered santonin on the food once a week for six weeks. Possibly, some of the newer, safe anthelmintic preparations containing piperazine derivatives may be equally effective. Eye infections are common, and are usually remedied by bathing the eye well with a 4 per cent. boric acid solution or warm cod-liver oil. Continuous discharge from the nose indicates lung infection, and as a primary measure the animal should be kept warm. Bleeding can be stopped by using Friar's Balsam, and care should be taken to prevent insects settling on open wounds.

WATER TORTOISES (TERRAPINS).

In Great Britain the tortoises that have become adapted to life in ponds and rivers are usually termed " terrapins," the name turtle being applied to marine forms. In the U.S.A. and Canada, however, not only the marine species but also terrapins and tortoises are all termed " turtles."

Several kinds of terrapin are available and capable of thriving in Great Britain. These include several American species, the European Pond Tortoise (*Emys orbicularis*), the Spanish Terrapin (*Clemmys leprosa*), the Caspian Terrapin (*Clemmys caspica*), and the Reeves' Terrapin (*Chinemys reevesii*), which hails from China and Japan.

The ideal place in which to keep terrapins is a garden pond within an enclosure. The pond should contain an " island " of dry ground on to which the animals can climb easily. The water should vary in depth, and at one point be at least 2 ft. deep. Provided that there is a suitable " island " the boundary walls of the pond can be upright to prevent escape. The final coat of cement should be smooth and mixed with a waterproofing agent. Shade should be available, not only on the island but also in some parts of the water. This may be provided by suitable plants.

Terrapins are almost entirely carnivorous, although the young of some species may take a little lettuce or other vegetable food. Suitable foods include *small* pieces of raw meat, raw liver (this should certainly be given from time to time), fish, and earthworms. Terrapins prefer to take their food in the water, and it is best to feed them individually if there are several, to ensure that each receives his proper share.

Water tortoises also hibernate. Some bury themselves in mud or sand at the bottom of their ponds, others will dig themselves into the earth in the island or banks of their pond, while others again may go to sleep in the box that, as in the case of land tortoises, should preferably be provided for them on part of their " land." Should they sleep at the bottom of the pond, it is as well to prevent freezing of the water. One means of doing this is to leave a log or logs floating on the surface. Moving these logs on cold mornings will help to break any ice formed and to prevent total freezing.

AQUARIUM FISH.

There are two types of aquaria—the cold-water, for fish from this and other temperate countries, and the heated, for tropical varieties of fish. Apart from the fact that a suitable heating mechanism—usually electric, with thermostatic control—has to be maintained for tropical aquaria, the general principles governing the two types are much the same. There is a certain amount of additional initial expense in setting up a heated aquarium—the running costs are not high—but in some respects tropical fish are easier to maintain than many of the cold-water varieties.

It should be emphasised at the outset that those who want to keep fish should invest in a proper aquarium and not in a " goldfish bowl," unless the latter be very large in relation to the fish to be kept. Far too many fish suffer from overcrowding or from lack of sufficient water surface. In the case of cold freshwater fish such as carp and goldfish (which need quite diffe conditions from tropical fish) it has been calcu that every " 1 in. of body " requires 1 sq. f water surface in order to obtain sufficient ox for respiration. Thus a fish the body of which the length minus the tail fins) is 4 in. will requi least 4 sq. ft. of water surface, *i.e.*, an area of 2 2 ft. Two such fish will require twice this area so on. In *The Right Way to Keep Pet Fish* b Dutta (6*s.*), it is pointed out that a goldfish sh normally live for twenty-five years in a suit pond, and grow to its full length of over 1 There are few indoor aquaria capable of suppo many full-grown goldfish in adequate condit and indeed it is recommended that dom varieties of goldfish such as shubunkins, fan veiltails, and orandas, which grow more slowly far better adapted to cold-water aquaria. pical fish of the varieties kept in aquaria usually much smaller, differ in their oxyge quirements, and can be kept in more cro conditions. Many have an average body le of only about 1½ in., and eighteen such fish m maintained in a suitably heated tank with an of water surface of 18 in. × 12 in.

A beginner should not only read good book the subject (including *Water Life* publicat but also consult experts and his local aquari dealer. Whatever aquarium is chosen, the ditions should be correct *before* any fish are i duced. Should fish be suddenly acquired, b a proper aquarium has been fitted up for t they should be kept in some temporary sufficiently capacious) quarters until the aqua is ready.

The instructions for installing and fitting u aquarium are usually supplied, and should followed carefully. The sand that is usu placed on the bottom should be thorou washed, and is best put in a little at a t Make sure that the inside of the aquariu thoroughly clean before anything at all is into it. Ornamental rocks may next be i duced, and great care should be taken to en that these are of the correct type, unlikely to l the fish physically or chemically. Water is added very gently indeed, and suitable plants In the case of large tanks the planting is done when the tank is only partly filled water, but in any event the plants thems should be kept wet all the time, or they quickly shrivel up. In the case of cold-w aquaria everything may now be left for a days—preferably a week or more—to ensure all is well, and to allow certain micro-organ that help form the food of the fish to dev In the case of heated aquaria it is necessary to ensure that the thermostat is working corr and that the temperature is remaining consta within very narrow limits. Here again advisable to wait at least a week before i ducing any fish. Should conditions " go wr before or after the fish are introduced, it is be start filling the tank all over again.

Fish should not be overfed, although re feeding is essential. Attention must be pa the feeding instructions issued with prep fish foods, and to details given by the suppli " live " foods. Provided fish are neither crowded not overfed, the amount of sedi that accumulates in the tank will not be exce but it should be siphoned away gently e month, or more often if necessary. Water by evaporation should be replaced, and in case of heated tanks especially, it is most desi that the added water be of the same tempera as that already in the tanks.

Certain species of water snail are often pl in aquaria to act as scavengers. It is nece to ensure that, if snails are kept, they are o right type, and it is important to consult ex on this matter.

Breeding is an interesting topic, there b both egg-laying and viviparous or " live-bear fish. The beginner is well advised to learn how to keep fish in healthy condition in aquarium before indulging in any planned b ing, and he should study the relevant informa in books on the subject.

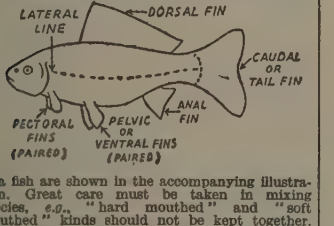
An aeration plant is often recommended o grounds that it will increase the fish-car

apacity of the aquarium. This is true up to a oint, but overcrowding may bring other troubles esides those connected with lack of sufficient xygen, and the golden rule is never to keep too many fish for the size of aquarium in question. nother factor to be remembered is that should he aerator break down it may leave the fish with ess oxygen than their proper requirement. It as been recommended that an aerator is best hought of as a stand-by, to be employed only in mergencies, *e.g.*, when for some reason extra sh have to be added to a tank already holding ll or almost all its proper capacity.

There are unfortunately many diseases of fish, nd as yet scientific knowledge concerning many f them is far less detailed than it should be. It is lear, however, that environmental factors are esponsible for many deaths or cases of unthrifti ess, and among the factors concerned may be isted: overcrowding, overfeeding, the provision f a diet that is qualitatively inadequate, lack of balance" in the aquarium leading to unsuitable onditions, dirt, too strong light, lead paint and oxious substances, that may somehow have ome into contact with the water (*e.g.*, from the ands of the person tending them) or been ab orbed from the atmosphere. One must be careful f such things as disinfectants, soaps, petrol, etc. n the case of tropical fish the temperature of the ater may be incorrect. Should fish troubles ccur, therefore, it is as well to consider these arious possibilities, although one should not esitate to seek professional advice where there ppears to be a case of infectious disease. An all g fish should certainly be removed from the ank (assuming that there are other fish present) nd given separate quarters of its own if such a ourse is feasible.

It is not intended to provide a description of the eparate diseases, although it may be mentioned hat such signs as the appearance of material esembling cotton-wool (actual fungal growths) nd "rotting" of the tail or fins, are among those hat should lead the owner to isolate affected fish nd to seek help immediately.

No attempt is made here to describe any of the nany different species and varieties of fish suit ble for private aquaria. Some of the "points"



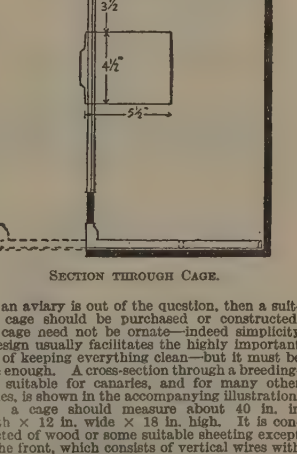
f a fish are shown in the accompanying illustra ion. Great care must be taken in mixing pecies, *e.g.*, "hard mouthed" and "soft nouthed" kinds should not be kept together. The temptation to put other species (*e.g.*, newts) vith aquarium fish must likewise be avoided.

CAGE BIRDS.

Very many species and varieties of birds are ow maintained successfully in captivity, and here exists in Great Britain a large and expand ng "cage-bird fancy," that caters for a consider ble proportion of the smaller birds adapted to age or aviary life. The increase in the numbers f budgerigars since the end of the Second World War has been phenomenal, and it was estimated during 1957 that the numbers of the species alone n the United Kingdom exceeded 6 millions, the corresponding figure for the U.S.A.—where the popular name is "parakeets"—being over 8 millions.

The different types and sizes of birds have different requirements, and in the space available t is not possible to do more than cover the general principles and to deal briefly with the special characteristics of the management of the more easily maintained species. The beginner is advised to restrict his attention to one of the better known species, *e.g.*, canaries or budgerigars, and not to attempt to maintain exotic varieties until he has acquired considerable experience.

Most species thrive best in aviaries, which may be indoor, outdoor, or of the combined "outdoor–indoor" type. An indoor aviary is usually all-wire and portable. The criticism of many such aviaries is that they tend to be high and narrow, whereas a fairly large floor-space is desirable. They should not be placed in cold or draughty places, nor too near a fire. If sited so as to receive much direct sunlight they must have adequate shelter. The wires must be close together, especially if smaller species are kept, a distance between them of about ½ in. being generally suitable. An outdoor aviary—suitable only for some species or at certain times in the case of others—should occupy a sunny position, although it too must include shade, and must be protected from winds. There ought in fact to be a sheltered portion, dry and well protected from the elements. The aviary must be strongly made and safe from all predators, including rats and mice. While it is often considered desirable to allow herbage to protrude through the wire-mesh floor, it is essential that the birds are never in close contact with wild rodents or their droppings. Most birds are highly susceptible to some forms of *salmonellosis* (see under mice and guinea-pigs), and can contract them in this way. It is advisable also that the roof of the aviary is solid: corrugated asbestos sheeting, projecting well clear of the edges of the uprights so as to prevent water and other matter from entering the interior, is excellent. The droppings of wild birds may be a potent source of bacterial infection or of internal parasites. To prevent close contact otherwise with wild birds, the wire or wire-netting "walls" of the aviary may be double. If an "outdoor–indoor" aviary is employed, there is usually an indoor flight cage, separated from the external portion either by a very light hanging door of suitable size, through which the birds can easily push their way, or by a sliding partition that the owner can operate as required.

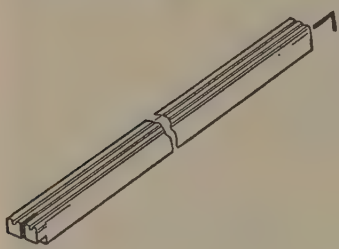


SECTION THROUGH CAGE.

If an aviary is out of the question, then a suitable cage should be purchased or constructed. The cage need not be ornate—indeed simplicity of design usually facilitates the highly important task of keeping everything clean—but it must be large enough. A cross-section through a breeding-cage suitable for canaries, and for many other species, is shown in the accompanying illustration. Such a cage should measure about 40 in. in length × 12 in. wide × 18 in. high. It is constructed of wood or some suitable sheeting except for the front, which consists of vertical wires with horizontal stays, and can be divided into two parts by means of a suitable partition containing a removable section made of wire. By this means the cock and hen canaries can be introduced into the separate sections and develop a courtship before being allowed to be together for actual mating. The cross-section indicates the site and size of the removable portion of the partition, and it shows also the removable tray that is such an

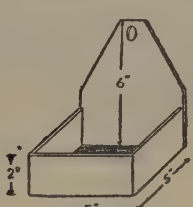
excellent fitting for almost any type of cage, and which greatly facilitates cleaning.

Whether an aviary or a cage is employed, it is essential to have proper fittings, including con-



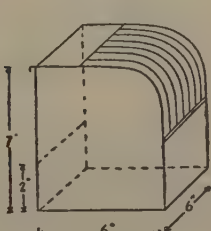
PERCH.

veniently placed drinking-troughs, feeding-trays and bird-baths, and good perches. Much unnecessary discomfort is brought about through the use of unsuitable perches, or ones that are incorrectly situated or not sufficiently "firm."



NESTING-BOX WITH PLAIN WOOD BOTTOM.

A suitable type of perch, of which there should be several in the cage or aviary, is shown in the accompanying illustration, and it should be of the appropriate dimensions for the size of bird. In the case of the larger canaries (Norwich and

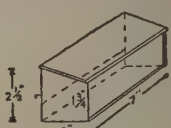


BIRD BATH.

Yorkshire), *e.g.*, the sectional measurements should be ¾ in. × ¾ in., whereas for a smaller canary (Border) they should be ½ in. × ½ in. The type of perch shown is easy to clean and does not possess awkward corners in which parasites may be harboured. The dimensions of a nesting box a bird-bath, and a feeding-tray suitable for canaries are also given in the accompan illustrations.

While wood is a convenient material for a and cage construction, it has, of course, se disadvantages. Out of doors it is best creos (lead paint must never be used for place which birds or other small animals are kept), indoors it is better lined with hard asbestos s ing. Metal is suitable—provided that it doe rust or corrode and that the environm conditions are warm enough.

In all cases a supply of clean, fresh water sh be available. Strict cleanliness should be served, and professional advice taken immedi if a bird is not thriving.



SEED TROUGH.

CANARIES (*Serinus canarius*).—These domesticated forms of the race of wild serin f in the Canary Islands, and may live up to twe five years. Many varieties are known, although most individuals are "canary yell other colours have been developed by fan Many books have been written about the ca although there is still much to be learned con ing its feeding and diseases—as is indeed the with almost all cage-birds. The system of ing generally recommended is based upo mixture of 2 or 3 parts of canary seed (whi rich in energy, and which is sometimes m with a little millet seed) to 1 part of summer seed, which is high in fat and protein. T seems to have been some difficulty in obta suitable rape seed in some areas since the The best is German summer rape or Rübsen Other seeds are employed as substitutes, o special purposes, *e.g.*, niger is usually adde breeding time, and linseed if there is any in tion of premature or soft (out-of-season) m Good proprietary seed mixtures are avail A little greenfood should be provided weekly, and a piece of cuttlefish bone p between the wires is a suitable source of cal Soft-bill food (containing boiled egg, dried yolk, dried flies, and ants' pupæ) is also re mended by many breeders, while others chopped egg alone. Others again favour especially for young birds.

Breeding is usually started late in March or in April, but not unless the daily shade tem ture is at least 50° F. The pairs shoul selected earlier than this and transferre breeding-cage, with the partition in pos By the middle of February the wire par may be installed so that the two birds ca one another. A little niger seed is usually a to the diet, while finely ground oystershe eggshell may be sprinkled on the floor. (Othe the floor may be covered with washed sand t not too fine and is free from dust.) Whe birds begin to feed one another through the they are ready for mating, and the partition be removed. The nest-box can then be ins and suitable nesting materials, *e.g.*, cow hai moss, placed in the cage. The incubation p is thirteen to fourteen days. After the egg laid some owners prefer to separate the cock the hen, but allow him to rejoin her afte young are all about eight to nine days old have opened their eyes. If it is desired th the chicks be hatched together, then one remove the first three eggs that are laid—us one egg is laid daily—and keep them in a b room temperature, substituting dummy egg them in the nest-box. On the afternoon o third day of laying they are returned to the box in place of the dummies.

hen the young chicks are able to feed for themes they should be provided with special food, as egg and bread crumbe and a little cracked ary seed. If the cock bird interferes with them, auses the hen to neglect them, he must be reed to his own section. Usually, however, all ; well, and the hen will go to the nest again n the first chicks are almost sixteen days old. e three or four broods may be raised in a on.

AXBILLS, FINCHES, AND OTHER SEED-TERS.—The canary is of course a finch, but t of the other "foreign finches" are considered dealers and writers together with other types seed-eating birds. Well over 30 species of *idavats, Buntings, Mannikins, Cardinals, Whyes, Weavers*, and *Finches* of various descriptions e been maintained successfully in captivity in at Britain. One of the most popular is the *ra finch* (*Taeniopygia castanotis*), from Austra- which has bred so successfully in this country t supplies no longer depend upon fresh importons, and which is already appearing in several ieties. The native bird, and many of its pendants, are grey and white, with red beaks. male bird has orange cheek-patches and nge flanks with white markings. The throat black barring on a white background, and eed the characteristic markings of the male e been the subject of interesting behaviour dies. The female lacks these special markings. species is hardy, and is capable of living in door aviaries all the year round, so long as it shelter from draughts or strong winds and quate facilities for roosting. If provided with t-boxes, the birds will attempt—often successy—to breed all the year round, so to avoid rbreeding it is better to remove these boxes in ter. A mixture of millet and canary seed ms the basis of their diet, which should be plemented with fresh greenfood, millet sprays, grit, and cuttlebone—and, of course, fresh er should be available. Another bird suitable the relatively uninitiated bird-keeper is the *ngalese* (a domestic variety of *Munia striata*). eems that these birds are the result of careful eding by the Japanese, and may be regarded fertile hybrids. Three main forms, the ocolate-and-White, the Fawn-and-White, and White, have been developed. These birds thrive in cages or in aviaries. As in the case Zebra Finches, they will attempt to breed all year round if provided with nest-boxes. ngalese are sociable birds, sometimes known the U.S.A. as Society Finches. They appear require less additional food than most species, iving on a mixture of canary and millet seed, ether with grit, cuttlebone, and an occasional let spray or item of greenstuff.

For details of these birds, and of the many ers from which a selection may be made, works reference should be consulted. Three very ful books, all published by Cage Birds, London, *Foreign Bird Keeping*, by Edward J. Boosey s.), *Foreign Birds for Beginners*, by D. H. S. don (10s. 6d.), and *Foreign Birds for Garden iaries*, by Alec Brooksbank (10s. 6d.).

BUDGERIGARS.—The increase in the popuity of this bird has been phenomenal, although to se who have experience of other birds as pets the sons are soon fairly obvious. Apart from the acity to talk, shown by many birds—especially les—kept alone and trained, there is a liveliness, noet a "cheekiness," and an apparent like of man companionship. The wild green budgeri- (*Melopsittacus undulatus*) exists in large nbers in the grassland and desert shrub regions Australia. The usual colour is grass green—it requently known as the Grass Parakeet—with ellow mask, with three black spots on either e. As a result of intensive breeding, a conerable number of colour varieties has been oduced, and the genetics of colour are a constant rce of interest to budgerigar breeders. A vast digerigar "fancy" has been built up in the ited Kingdom, the U.S.A., and other countries. l World Budgerigar Congresses are held eve. y years. Budgerigars will thrive in outdoo. aries all the year round, but the vast majority are kept as indoor pets in cages or small aviaries. The cages can be similar to those used for canaries, and care should be taken that the perches are of the correct diameter. If nest-boxes are put up, and the environmental conditions are suitable, budgerigars suitably paired will breed at almost any time of the year. It is customary, however, to restrict breeding to the spring, summer, and early autumn. Overbreeding may lead to difficulties, including the production of "runners" or "French moult." The sexes may normally be distinguished, at any rate in mature individuals, by the colour of the cere at the base of the beak, which is blue in males and brown in females. Males may lose their colour if not in good condition and for other reasons.

There are now many proprietary seeds mixtures, but some owners prefer to make up their own mixtures of millet (usually mixing small yellow and large white varieties) and canary seed. Millet sprays, fresh greenfood, good grit, and cuttlebone are all desirable, and it is important that the correct size and consistency of grit be chosen. Variety in "extras" to the basal seeds diet is probably important, for the captive bird has not the same opportunities as its wild ancestors for ranging widely for, possibly, important trace items of food. Breeding birds secrete a "milk," comparable with the crop milk of pigeons and some other birds, and this is of importance in the early feeding of the young.

Most healthy budgerigars seem to live to the age of 5–7 years or more, and considerably greater ages have been attained in captivity.

Such is the development of the budgerigar fancy that most equipment as well as food can be obtained ready for use. The playful habits of budgerigars have led to their being given tabletennis balls or a variety of small toys to play with, while some forms of food are supplied as budgerigar bells or otherwise in special shapes that seem to amuse the birds as they take the constituent seed from them.

The study of budgerigar diseases is in its infancy, but already some important facts have become realised. *French moult* is certainly reproducible by overbreeding, and may be linked with deficiencies in the ability of the parent birds to feed their young—or to hand over to them at the time of laying sufficient nutritional reserves to carry them through hatching and parental feeding until the time that they can fend for themselves. A deficiency in the "milk" has been shown in some cases, and may be generally true. Large chicks can be produced by killing off or removing all but a single member of the clutch, and allowing the parents to deal with it alone.

A mite infestation, due to *Cnemidocoptes pilae*, may give rise to *Scaly face*, *Scaly beak*, or *Scaly leg*, for which veterinary treatment is now available. Another condition, known as *Brown hypertrophy of the cere*, is characterised by thickening and darkening of the surface of the cere. In the early stages it is sometimes thought that the bird is changing its sex. There is no known successful treatment at the time of writing, and if the overgrowth is cut away it will only reform. There are various disturbances of the *digestive tract*, and some of these may be associated with inability to stand properly.

There are many treatises on the budgerigar. A useful little work is *Budgerigar Guide*, by Cessa Feyerbrand (Fond du Lac, Wisconsin: All-Pets Magazine).

LOVEBIRDS AND PARROTLETS are also members of the parrot family, and while they are unlikely to equal the budgerigar in popularity, they are nevertheless interesting birds that are being kept in increasing numbers as pets. Lovebirds, of the genus *Agapornis*, are African in origin, and some six species are commonly kept in captivity. Parrotlets derive from South America, the commonest species being the Guiana Parrotlet, *Forpus passerinus*. Both types of bird are relatively simple to maintain in aviaries or large cages, and their basal diet (which should be supplemented widely) is a mixture of millet and canary seed. They are hardy and vigorous creatures, many details of which are to be found in condensed form in *Lovebirds and Parrotlets*, by C. P. Luke (London: Cage Birds, 8s. 6d.).
